SUBJECT INDEX

Abdominal Brushes of Male Noctuid Lepidoptera Pheromones from the (R T Aplin and M C Birch), 1167
Aberations during Normal Epithelial Proliferation Chromosome (J G Forsberg and B Lannerstad), 568
Abercrombie, M , and Brachet, Jean (editors) Advances in Morphogenesis, *review* by Michael Begg, 293
Ability of Haemotopoietic Spleen Colonies to form Macrophages *in vitro* (M Virolainen and V Defendi), 1069
  of Leucocytes to recognize some Foreign Gamma Globulins during Pinocytosis (C Bona and Gr Ghyka), 172
Abnormalities in the Electrocardiograms of Young Sheep and Lambs grazing Natural Pastures low in Selenium (K O Godwin), 1275
ABO Blood Groups, Secretor Status, and Intestinal Mucosal Concentrations of Alkaline Phosphatase (M J S Langman, A Constantinopoulos and I A D Bouchier), 863
Aborigines of Australia Unusual Distribution of Red Cell Acid Phosphatase among (L Y C Lai), 1186
Abrahams, Ralph, and Robbin, Joel Transversal Mappings and Flows, *review* by L S Goddard, 485
Absence of Thymus in a Mouse Mutant (E M Pantelouris), 370
  of β-Globin Synthesis and Excess of α-Globin Synthesis in Homozygous β-Thalassaemic Subjects from the Ferrara Region (F Conconi, A Bargellesi, S Pontremoli, V Vigi, S Volpato and D Gaburro), 259
Absorption Bands at 4890 Å and 4760 Å at Different Galactic Longitudes Profiles of the Unidentified Interstellar (Harry Seddon), 932
  Coefficients for the Forbidden Lines of Atomic Sulphur Wavelengths and (J W McConkey, D J Burns, I A Moran and J A Kernahan), 538
  Distribution of Small Scale Interstellar (K Ishida and K Akabane), 433
  in the Wavelength Range 2mm to 300 μm Observations of Atmospheric (H A Gebbie and W J Burroughs), 1241
  of *d*-Glucose by the Rabbit Jejunum during Cholera Toxin-induced Diarrhoea (Harold A Serebro, Theodore M Bayless, Thomas R Hendrix, Frank L Iber and Thomas McGonagle), 1272
  of Excited Molecules in Iron Aerosols Spectral (H Jagger and H -G Kieschke), 934
  Spectrum of Bromine Chloride Visible (M A A Clyne and J A Coxon), 448
Accelerated Visual Motion Electroencephalogram Potentials evoked by (D M MacKay and W J Rietveld), 677
Acceleration Produced Electric Fields in Charcoal Bodies (P A Dunkerley), 52
Accelerator, plans for big machine at Weston, Illinois, *news*, 4
Accelerators of the future, *news*, 706
Accidents, cost to the community, *news*, 212
Accumulation of Dry Matter by *Chrysanthemum morifolium* after Flower Removal (K E Cocksjull and A P Hughes), 979
Acetabularia Effect of Kinetin on the Phosphatase Enzymes of (T Spencer), 62
Acetate by Mercury-resistant Bacteria Stimulative Vapourization of Phenylmercuric (K Tonomura, K Maeda, F Futai, T Nakagami and M Yamada), 644
Acetic Acid from ^{14}C-Tryptophan by Rat Pineal Glands in Organ Culture Formation of Melatonin and 5-Hydroxyindole (Richard J Wurtman, Frances Larin, Julius Axelrod, Harvey M Schien and Katherine Rosasco), 953
  Heterochromatic Segments in *Vicia* revealed by Treatment with HCl-(Shin Takehisa), 567
Acetylcholine in Rat Brain Regional Distribution of Tritiated (S Z Kramer, J Seifter and B Bhagat), 184
  Sensitivity of the Mammalian Heart *in situ* and *in vitro* Effect of Excess Magnesium on Vagal Inhibition and (G C Somjen and E N Baskerville), 679
Acid Coal Mine Spoils Availability of Nitrogen to Plants in (S M Cornwell and E L Stone), 768
  Mucopolysaccharides with isolated Amyloid Fibrils Association of (C A Pennock), 753
  Phosphatase among Aborigines of Australia Unusual Distribution of Red Cell (L Y C Lai), 1186
Acid-soluble Collagen Intermolecular Relationship between Neutral-salt-soluble and (R J Davidson and D R Cooper), 168
Acidosis Concentrations of Metabolic Intermediates in Kidneys of Rats with Metabolic (G A O Alleyne), 847
Actinomycin D and DNA Interaction between Model Compounds of DNA Dependent RNA Synthesis (F Ascoli and M Savino), 162
  Interaction between Model Compounds of Physico-chemical Studies (F Ascoli, M Savino and A M Liquori), 162, *erratum*, 394
Action after the Dainton Reports (L Rosenhead), 806
  of Atomic Hydrogen on Aqueous Bacteriophage T_7 (David Dewey and Gabriel Stein), 351
  of Bacteriophages obtained from *Corynebacterium diphtheriae* on *C ulcerans* and *C ovis* (H R Carne), 1066
  of Potato Peel Extracts in modifying Tuber Dormancy (M G Walker), 878
  of Insulin on Sodium Efflux from the Toad Oocyte (E E Bittar, D A T Dick and D J Fry), 1280
  of Hydroxyurea on Multiplication of Influenza Virus in Mammalian Cells (W C Bell and H F Maassab), 646
  of Iontophoretically Applied Tetrodotoxin on Cortical Nerve Cells (J W Phillis, A K Tebecis and D H York), 271
  of Procaine on Calcium Efflux from Frog Nerve and Muscle (Albert S Kuperman, Bella T Altura and Judith A Chezar), 672
  Potentials induced in Biomolecular Lipid Membranes (Paul Mueller and Donald O Rudin), 713
  Potentials Role of Calcium in the Production of, Calcium Spikes of Nerve Cell Membrane (K Koketsu and S Nishi), 468
Activation of Malathion by the Locust Bodywall (Hafiz Ahmed and B G Gardiner), 776
  of Small Molecules by Transition Metal Ions and their Complexes (R Mason), 543
Acyloligopeptide Methyl (N-) Esters by Mass Spectrometry Detection and Location of N-Methyl-amino-acid Residues in (B C Das, S D Gero and E Lederer), 547
Adaptation Phenomena in Phototaxis, *Chlamudomonas* (A M Mayer), 875
Adenosine Diphosphate of the Thrombocytopenia induced in Rabbits by Collagen or Thrombin Inhibition by (Dorothy Busfield and E G Tomich), 376
  Monophosphate, Vasopression, Theophylline and, on Short-circuit Current across Isolated Rabbit Ileal Mucosa Effects of (Michael Field, Gerald R Plotkin and William Silen), 469
  Phosphates and Fibrinogen as a Cause of Platelet Aggregation Physico-chemical Interaction between (D A Smink, H E J Kruisheer, and C J G Bottcher), 375
Adenosinetriphosphatase Activity in Liver Mitochondria Effect of Phenylhydrazine and hydrolysed Glucose Cycloacetoacetate on (M C Nath, T G Reddi and N Nath), 552
Adenovirus-infected Cells treated with Hydroxyurea High Titre T Antigen with Minimal Amounts of Structural Antigen in (Jay A Levy, Robert J Huebner, Jerome Kern and Raymond V Gilden), 744
Adjuvanicity of Vitamin A (D W Dresser), 527
Admiralty Hydrographic Service, 1795–1919 The (Vice-Admiral Sir Archibald Day), *review* by Margaret Deacon, 783
Admissions and school curricula, Oxbridge investigates, *news*, 500
Adoptive Suckling in the Grey Seal (E A Smith), 762
Adrenaline on Oxygen Consumption Rate and Arterial Blood Pressure in the Newborn Pig Effects of Noradrenaline and (J LeBlanc and L E Mount), 77
Adrenergic β-Blocking Agents in inducing Histamine Sensitivity in Mice Efficacy of (R K Bergman and J Munoz), 1173
  Feeding System of Rat Hypothalamus Amphetamine Anorexia by Direct Action on the (D A Booth), 869
  Receptor Evidence favouring the Existence of a Single (G Kunos and M Szentivanyi), 1077
  Responses Increased Receptor Utilization Mechanism of Cocaine Potentiation (K Nakatsu and R J Reiffenstein), 1276
Adsorption Efficiency in the Collision of Molecular Oxygen with Clean Tungsten Surfaces (A M Horgan and D A King), 60
  of Wetting Agents and Detergents Rates of (Pasupati Mukerjee), 1046
Adult Mice Mechanisms in Early and Late Phases of Tolerance induced by Parabiosis in (N W Nisbet), 265
Advances in Morphogenesis (edited by M Abercrombie and Jean Brachet), *review* by Michael Begg, 293
AEA cuts, *parliamentary news*, 705
Aedes detritus Haliday Pre-gravid Phase of Ovarian Development in (M W Service), 681
Aegilops comosa into Wheat by Genetically Induced Homoeologous Recombination Introduction of Yellow Rust Resistance of (Ralph Riley, Victor Chapman and Roy Johnson), 383
AEI redundancies after GEC merger, *news*, 496
  to build US turbine, *news*, 211
Aerosol Attenuation in the Chest Wall of 20 keV X-rays from an Inhaled Radioactive (J Rundo, B T Taylor, D V Booker, D Newton and D Scargill), 643
Aerosols Spectral Absorption of Excited Molecules in Iron (H Jager and H -G Kieschke), 834
Afganistan Sarcomas in (Leslie H Sobin), 1072
Aflatoxins Isolation of a New Toxin from Cultures of *Aspergillus flavus* (J V Rodericks, Kenneth R Henery-Logan, A D Campbell, L Stoloff and M Jacqueline Verrett), 668
Africa Drifting and Rifting of (R W Girdler), 1102
Age of the Upper Boulder Clay Glaciation in the Midlands (E G Poole), 1137
  report on Old, *news*, 1201
  Research Feasibility in (A Comfort), 320
Agglutinin in Extracts of Wheat Germ Specificity of the (Rosemary Liske and D Franks), 860
Agglutinins and Mitosis Plant (H J Downing, G C M Kemp and M A Denborough), 654
Agglutination of Bovine Erythrocytes infected with *Babesia argentina* *In vitro* (J A Curnow), 267
Aggregation Physico-chemical Interaction between Adenosine Phosphates and Fibrinogen as a Cause of Platelet (D A Smink, H E J Kruisheer and C E G Bottcher), 373
Aggregator of Blood Platelets Powerful New—2-Chloroadenosine-5′-diphosphate (M Helen Maguire and Frank Michal), 571
Agkistrodon from Asia and the North American Continent Phylogenetic Relationships among Venomous Snakes of the Genus (Anthony T Tu and Bryant L Adams), 761
Agonists on the Isolated Guinea-pig Ileum Sites of Action of some Partial (K Takagi, I Takayanagi, F Taga and K Nishino), 573
Aigrain, Dr Pierre New head of French research delegation, *news*, 497
AIP Seizures in Experimental Porphyria (Nechama S Kowower and Rica A Rock), 565
Air Showers at 520 MHz Radio Pulses from Extensive (D J Fegan and P J Slevin), 440
Akademgorodok, Russian scientific city (Angela Croome), *news*, 796
Alamethicin Action Potentials induced in Biomolecular Lipid Membranes (Paul Mueller and Donald O Rudin), 713
Alaninuria (β-) in Patients with Tuberculosis (Tetsuto Takao, Tsutomu Yasumitsu, Tohru Uozumi, Yasuo Kakimoto and Akira Kanazawa), 365

Albumin Maku A New Variant of Human Serum Albumin (L R Weitkamp and N A Chagnon), 759
Synthesis, Regulation of, and Catabolism by Alteration of Dietary Protein (R Kirsch, Lesley Frith, Elizabeth Black and R Hoffenberg), 578
Alcohol, breath tests modified, *news*, 1091
Aldermaston declassification called for, *parliamentary news*, 1204
Alfven's Critical Velocity Hypothesis (J C Sherman), 341
Alga Production of Hydrogen Sulphide by a Termophilic Blue-green (Richard P Sheridan and Richard W Castenholz), 1063
Algae classified Symposium, *news*, 312
New Glycolipid Specific to Nitrogen-fixing Blue-green (B W Nichols and B J B Wood), 767
Algebraic Theory of Particle Physics (Yuval Ne'eman), *review* by P T Matthews, 197
Alginates Binding of Calcium and Strontium by (James T Triffitt), 457
Alignment Hypothesis as the Reason for the Mosaic Unit Phenomenon Test of the (R E M Moore), 482
Alimentary Lipaemia in Rats Genetic Influence on (Meyer Friedman and Sanford O Byers), 235
Alkali Feldspar Megacrysts and their Inclusions in Cornubian Granites Petrogenetic Significance of (B Booth), 1036
Metals Co-ordination Compounds of, with 8-Hydroxyquinoline and Isonitrosoacetophenone (A K Banerjee, A J Layton, R S Nyholm and Mary R Truter), 1147
Alkaline Earth Radioisotopes in Adult Bone Radial Diffusion and Power Function Retention of (John H Marshall and Claude Onkelinx), 742
Phosphatase ABO Blood Groups, Secretor Status and Intestinal Mucosal Concentrations of (M J S Langman, A Constantinopoulos and I A D Bouchier), 863
Phosphatases, Homologous, and Homologous Loci in Two Sibling Species of European Anopheline Mosquitoes (Umberto Bianchi), 382
Alkaloids Toxicity of Pyrrolizidine (A R Mattocks), 723
All Change at Cal? (Nicholas Wade), 1005
Allergens Inhibition of Leucine and Lysine Aminopeptidase by Atopic (L Berrens), 664
Allergy Mites in Bedroom Air (A M Cunnington and P H Gregory), 1271
Allocation of Trivial Names to the Gibberellins Proposed Procedure for the (J Macmillan and N Takahashi), 170
Allosterism, *news*, 903
Alloys Preparation of Fibre Reinforced Nickel-Gold, using a Solid State Reaction (J Ordonez, A A Johnson and K Mukherjee), 443
Allyl Ligand in some Allyl-Palladium Complexes Stereochemistry of the (R Mason and A G Wheeler), 1253
Alpenrhein and some other Rivers General Relationship between Suspended Sediment Concentration and Water Discharge in the (G Muller and U Forstner), 244
Alpha$_2$-globulin and Alpha$_2$-macroglobulin of Other Mammals Relation between Rat Slow (Werner G Heim), 1057
Aluminium Metals on the Lunar Surface (K H Sun), 243
smelter, Swiss tender, *news*, 116
smelters and the coal board, *news*, 397, 398
with coal power, *news*, 304
Amantadine Combined Inhibition of Influenza Virus Reproduction in Cell Culture using Interferon and (S V Lavrov, E I Eremkina, T G Orlova, G A Galegov, V D Soloviev and V M Zhdanov), 856
Amber Suppression A Nucleotide Change in the Anticodon of a Tyrosine Transfer RNA (Howard M Goodman, John Abelson, Arthur Landy, S Brenner and J D Smith), 1019
American Physical Society and political issues, *news*, 494, 502
schools with problems, *news*, 698
science and effects of 1969 budget, *news*, 505
Science in the Age of Jackson (George H Daniels), *review* by Marie Boas Hall, 983
Amine Depletor Treatment Female Copulatory Behaviour in Male and Androgenized Female Rats after Oestrogen/ (Bengt J Meyerson), 683
Amino-acid Composition of "Tubulin" constituting Microtubules of Sperm Flagella (Hideo Mohri), 1053
from *Indigofera spicata*, Indospicine A New Hepatotoxic (M P Hegarty and A W Pound), 354
Amino-acids and Metal Complexes Stereoselective Interaction of (R D Gillard, P R Mitchell and H L Roberts), 949
in cell walls, *news*, 1100
Molecular Interactions between Tryptophan and Nucleic Acid Components in Frozen Aqueous Solutions (Thérèse Montenay-Garestier and Claude Hélène), 844
Amino (*β*-) Laevulinic Acid to Porphobilinogen by Different Tissues of the Polychaete Annelid *Neoamphitrite figulus* Conversion of (R Phillips Dales), 553
Aminopeptidase by Atopic Allergens Inhibition of Leucine and Lysine (L Berrens), 664
Ammonia-Oxygen Fuel Cell (E J Cairns, E L Simons and A D Tevebaugh), 780
Amnesic Patients New Method of Testing Long-term Retention with Special Reference to (Elizabeth K Warrington and L Weiskrantz), 973
Amoeba proteus on Treatment with Polyionic Substances Size changes in Isolated Nuclei of (W Korohoda, J A Forrester, K G Moreman and E J Ambrose), 615
Amoebae, how immortal?, *news*, 706
Amphetamine Anorexia by Direct Action on the Adrenergic Feeding System of Rat Hypothalamus (D A Booth), 869
Amyloid Fibrils Association of Acid Mucopolysaccharides with isolated (C A Pennock), 753
Analogue System for Active Transport using Charged Membranes Transport of Ions against their Concentration Gradients in an (Russell Paterson), 545
Analogues of Polynucleotides Synthetic (M H Halford and A S Jones), 639
Analysis of Antibodies against Synthetic Angiotensin II by the Passive Haemagglutination Technique (Felix M Dietrich and Hannes Frischknecht), 264
Androgenized Female Rats after Oestrogen/Amine Depletor Treatment Female Copulatory Behaviour in Male and (Bengt J Meyerson), 683
Anelastic and Dielectric Effects in Polymeric Solids (N G McCrum, B E Read and G Williams), *review* by R P Sheldon, 883
Angiotensin on Uptake of Noradrenaline in Tissues of Pithed Rats Effect of Cocaine, Desipramine and (D T Pals and F D Masucci), 772, *erratum*, 1084
Radioimmunoassay of (H J G Hollermans, J van der Meer and J L Touber), 277
II by the Passive Haemagglutination Technique Analysis of Antibodies against Synthetic (Felix M Dietrich and Hannes Frischknecht), 264
-Renin System Peptide Inhibitors of the (T Kokubu, E Ueda, S Fujimoto, K Hiwada, A Kato, H Akutsu, Y Yamamura, S Saito and T Mizoguchi), 456
Angling and the cigarette manufacturers, *news*, 503
Anglo-Saxon Problems in Science and Technology, *news*, 1
Anguis fragilis Fine Structure of the Sensory Endings in the Vomero-nasal Organ of the Slow-worm (L H Bannister), 275
Anisotropic Soft X-ray Background Flux Detection of (C S Bowyer, G B Field and J E Mack), 32, *erratum*, 296
Annealing of Single Phase Polycrystalline Sulphide Ores (R L Stanton and Helen Gorman), 160
Annelid *Neoamphitrite figulus* Conversion of *δ*-Amino Laevulinic Acid to Porphobilinogen by Different Tissues of the Polychaete (R Phillips Dales), 553
Annual Review of Genetics, Vol I (edited by Herschel L Roman), *review* by G Pontecorvo, 885
Anopheles gambiae Giles in the Sudan Dry Season Biology of (Salah M Omer and J L Cloudsley-Thompson), 879
Anopheline Mosquitoes Homologous Alkaline Phosphatases and Homologous Loci in Two Sibling Species of European (Umberto Bianchi), 381
Anorexia by Direct Action on the Adrenergic Feeding System of Rat Hypothalamus Amphetamine (D A Booth), 869
Antarctic evidence Origin of Nitrate Deposits (G G C Claridge and I B Campbell), 428
Antagonism of Presynaptic Inhibition in the Cuneate Nucleus by Picrotoxin (N R Banna and S J Jabbur), 83
Antarctica Palaeomagnetism of a Stratiform Intrusion in the Pensacola Mountains (Myrl E Beck, jun , Arthur B Ford and Walter W Boyd), 535
Antelopes Historical Zoogeography of (A W Gentry), 874
Antiamoebin L-2-Amino-3-phenyl-1-propanol (L-Phenylalaninol) as a Constituent of a Fungal Metabolite (P V Deshmukh and M G Vaidya), 849
Antibiotics as Cation Carriers, Cyclic, *news*, 1209
Antibodies against Synthetic Angiotensin II by the Passive Haemagglutination Technique Analysis of (Felix M Dietrich and Hannes Frischknecht), 264
Detection of Insulin Precipitating (M Ceska), 356
Antibody and Complement Passive Sensitization of *Salmonella adelaide* to the Bactericidal Action of (D Rowley and Keven J Turner), 657
Purification of Antilymphocytic (M F A Woodruff), 821
-forming Cells during the Early Stages of the Immune Response DNA Synthesis in the Development of (A Szenberg and A J Cunningham), 747
Gamma G4-Globulin, causing Inhibition of Clotting Factor VIII (Burton R Andersen and William D Terry), 174
Reaction Measurement of an Antigen-, by a Static Method Utilizing a Porous Gel (Claude Sculeil and Alfred Nisonoff), 144
Synthesis in Chickens bursectomized as Embryos Gamma Globulin Production and (Pierson J Van Alten, William A Cain, Robert A Good and Max D Cooper), 358
Technique Location of Gamma Globulin in the Endocardium in Rheumatic Heart Disease by the Ferritin-labelled (R Lannigan and S Zaki), 173
Anticodon of a Tyrosine Transfer RNA Amber Supression a Nucleotide Change in the (Howard Goodman, John Abelson, Arthur Landy, S Brenner and J D Smith), 1019
Antigen-Antibody Reaction by a Static Method utilizing a Porous Gel Measurement of an (Claude Sculeil and Alfred Nisonoff), 144
Structural, in Adenovirus-infected Cells treated with Hydroxyurea, High Titre T Antigen with Minimal Amounts of (Jay A Levy, Robert J Huebner, Jerome Kern and Raymond V Gilden), 744
Antigenic Stimulation in Adult Rats Proliferation of Mast Cells after (John J Miller III and Leonard J Cole), 263
Stimulus Normal Immune Responses of Bursaless Chickens to a Secondary (M Elaine Rose and Eva Orland), 231
Antigens in DMBA-induced Leukaemia of Rats Lack of Complement Fixing (Nehama Sharon and Morris Pollard), 363
RNA in Mouse Cells exposed to Different (Karel Raska, jun and Edward P Cohen), 721
Anti-gonadotropin Sera on Developing Chick Embryo Evidence from Effects of Morphogenetic Properties of Follicle-Stimulating Hormone (Gajanan V Sherbet and M S Lakshmi), 1257
Anti-lymphocyte Globulin Immunosuppressive Effects of Lymphoid Cell Proliferation in Mice receiving (A M Denman, Evelyn J Denman and E J Holborow), 177
Sera *In vitro* Detection of Immunosuppressive Activity of (J F Bach and B Antione), 658
Serum Erasure of Immunological Memory with (Eugene Lance), 557
Serum with Haemopoietic Stem Cells Cross-reaction of (E O Field and J E Gibbs), 561
Antilymphocytic Antibody Purification of (M F A Woodruff), 821
IgG on Sensitized Spleen Cells *In vivo* and *in vitro* Effect of (Keith James), 261
Anti-metabolic Extract from the Brain of *Protopterus aethiopicus* (Henry Swan, Dalton Jenkins and Kerwin Knox), 671
Antimony on Disordered Substrates Production of Epitaxial Films of (K G Robbins and J M Thomas), 1251
Antioxidant Metabolism, *news*, 1004
Antisera Numerical Taxonomy and Influenza B Virus (Anna M Lee), 620
Antisymmetric Raman Scattering Tensor Experimental Observation of an (J A Koningstein and O S Mortensen), 445
Anti-tumour Activity of S-Carbamyl-cysteine (Richard H Adamson), 751
Ants, Possibility of Investigating Movement in a Group of, by the Mossbauer Effect (T Bonchev, I Vassilev, T Sapundzhiev and M Etimov), 96
"Anxiety" Effects of Drugs on Conditioned (Derek Blackman), 769
Aortic Valve Mechanism of Closure of the (B J Bellhouse and F H Bellhouse), 86
Apparent HeLa Cell Contamination of Human Heteroploid Cell Lines (Stanley M Gartler), 750
Appetite reduction Amphetamine Anorexia by Direct Action on the Adrenergic Feeding System of Rat Hypothalamus (D A Booth), 869
Application of Laser Interferometry to Physiological Studies of Excitable Tissues (R Sandlin, L Lerman, W Barry and I Tasaki), 575
Applications of Magnetic Circular Dichroism and Optical Rotatory Dispersion Measurements (B Briat and Carl Djerassi), 918
Aqueous Humour Vitamin B_{12} Content of (C I Phillips, R G Ainley, P Van Peborgh, J Watson-Williams and A C Bottomley), 67
Substrates at Low Surface Pressures Circulation within Monolayer Films on (E R Moss, D M Himmelblau, R S Schechter and R L Pitzer), 349
Arbovirus through 'Millipore' Membranes Filtration of (J Casals), 648
Are the Optical Luminosity Fluctuations of 3C 273 Random? (Tom Manwell and M Simon), 931
Argence, Emile, and Kahan, Theo Theory of Waveguides and Cavity Resonators, *review* by P J B Clarricoats, 108
Argon Characteristic Energy Loss of Electrons transmitted through (G C Hale and J B Hasted), 945
Sorption at 77 4°K on a Microporous Glass (B Evans and T E White), 881
Argyle, Michael Psychology and Social Problems, *review* by K T Strongman, 586
Arm Movement Response of Neurones in the Motor Cortex during Performance of a Simple Repetitive (Erich S Luschei, Robert A Johnson and Mitchell Glickstein, 190)

Arterial Blood Pressure in the Newborn Pit Effects of Noradrenaline and Adrenaline on Oxygen Consumption Rate and (J LeBlanc and L E Mount), 77
Artificial Reconstruction of a Species of Fern, *Asplenium adulterinum* (J D Lovis), 1163
Asbestosis report, *news*, 120
Asparaginase (L-) Activity in Human and Animal Sera (Maureen B Lee and John M Bridges), 758
Asparagus cells cultured *in vitro* Growth and Morphogenesis of (Cecile Wilmar and Marja Hellendoorn), 369
Aspergillus flavus Isolation of a New Toxin from Cultures of (J V Rodericks, Kenneth R Henery-Logan, A D Campbell, L Stoloff and M Jacqueline Verrett), 668
Aspleium adulterinum Artificial Reconstruction of a Species of Fern (J D Lovis), 1163
Aspartate transcarbamylase, sub-unit structure, *news*, 902
Association between *Pandalus borealis* and Fine-grained Sediments off Northumberland (P J Warren and R W Sheldon), 579
  of Acid Mucopolysaccharides with isolated Amyloid Fibrils (C A Pennock), 753
  of Commonwealth universities, report, *news*, 500
  Radiative Possible Important Loss Process for Metallic Ions in the Ionosphere (W Swider, jun), 438
Asthma and the High Frequency Sound Environment (R K Mason), 360
Astronomers, general assembly of International Union, advance notice, *news*, 599
Astronomical Society, Royal, awards, *news*, 212
Astronomy and space research, budgets examined, *news*, 991
  Old and New (Ernest Agar Beet), *review* by J D North, 389
Attenuation in the Chest Wall of 20 keV X-rays from an Inhaled Radioactive Aerosol (J Rundo, B T Taylor, D V Booker, D Newton and D Scargill), 643
Atlantic Ocean Characterization of Carbonaceous Material from the Puerto Rico Trench of the (R A Friedel and A J Nalwalk), 345
Atlantic Salmon Disease Fungus (L G Willoughby), 872
  Salmon Mycological Aspects of Diseased (Mary R Stuart and Hubert T Fuller), 90
Atlas of Electron Spin Resonance Spectra (B J H Bielski and J M Gebicki), *review* by M C R Symons, 689
Atmospheric Absorption in the Wavelength Range 2mm to 300 *u*m Observations of (H A Gebbie and W J Burroughs), 1241
  Layer, Superadiabatic, on Venus, as inferred from the Venera-4 Probe Measurements (A D Anderson), 627
Atomic Hydrogen on Aqueous Bacteriophage *T*-, Action of (David Dewey and Gabriel Stein), 351
  Oxygen in upper atmosphere, *news*, 310
  Sulphur Wavelengths and Relative A-Coefficients for the Forbidden Lines of (J W McConkey, D J Burns, I A Moran and J A Kernahan), 538
Atopic Allergens Inhibition of Leucine and Lysine Aminopeptidase by (L Berrens), 664
ATPase, Steroids and, *news*, 508
Aubrey Jones on university pay, *news*, 3
Auditor-General on university funds, *news*, 496
Auricle Frequency Conduction Velocity and Rate of Depolarization in Rabbit (J W Viersma, L N Bouman and M Mater), 1177
Austenite and Mineral Oil in Lubricant Failure Role of (W Grew and A Cameron), 481
Australian, Native, and Introduced Species of Animals, Physiological, Morphological and Behavioural Adaptation to Sodium Deficient Environment by Wild (J R Blair-West, J P Coghlan, D A Denton, J R Nelson, Elspeth Orchard, B A Scroggins, R D Wright, K Myers and C L Junqueira), 922
Autumnization and its Genetic Interpretation (Sandor Raijki), *review* by Ralph Riley, 291
Auxin by Detached Leaves Production of (A R Sheldrake and D H Northcote), 195
  Catabolism of *Lactobacillus bulgaricus* Effect of β-Indolylacetic Acid on the Growth and the (P E Pilet and B Blanc), 285
Availability of Nitrogen to Plants in Acid Coal Mine Spoils (S M Cornwell and E L Stone), 768
Avian Embryo Biochemistry of the (Alexis L Romamoff), *review* by John McKenzie, 107
Avidins and Lysozymes Evidence for a Genetic Relationship between (N M Green), 254
Axoplasmic Transport of ^{14}C-Noradrenaline and Protein in Splenic Nerves (B G Livett, L B Green and L Austin), 278
Azulene-type Radical obtained on Heating 3,4-Benzpyrene Possible Formation of an (W F Forbes and J C Robinson), 550

B_{12}, Vitamin, Content of Aqueous Humour (C I Phillips, R G Ainley, P Van Peborgh, E J Watson-Williams and A C Bottomley), 67

  price increases and new 360 computer, *news*, 115
Identification of Bradykinin New Test for Biological (H Edery), 70
  of Rhinovirus Strain *D C* (R M Conant, V V Hamparian, E J Stott and D A J Tyrrell), 1264
Ignimbrites Second Additional Theory of Origin of Fiamme in (Alexander R McBirney), 938
IgG on Sensitized Spleen Cells *In vivo* and *in vitro* Effect of Anti-lymphocytic (Keith James), 261
Ileal Mucosa Effects of Vasopressin, Theophylline and Adenosine Monophosphate on Short-circuit Current across Isolated Rabbit (Michael Field, Gerald R Plotkin and William Silen), 469
Ileum Sites of Action of some Partial Agonists on the Isolated Guinea-pig (K Takagi, I Takayanagi, F Taga and K Nishino), 573
Immediate Circulatory Response to High Altitude Hypoxia in Man (Sujoy B Roy, J S Guleria, P K Khanna, J R Talwar, S C Manchanda, J N Pande, V S Kaushik, P S Subba and J E Wood), 1177
Immune Competence Cellular, of Spleen Bursa and Thymus Cells (W A Cain, M D Cooper and R A Good), 87
  Haemolysis Reaction of the Terminal Complement Component (O Gotze, I Haupt and H Fischer), 1165
  Response DNA Synthesis in the Development of Antibody-forming Cells during the Early Stages of (A Szenberg and A J Cunningham), 747
  Response Induction of the Primary (I Mackay Murray), 430
  Response of Rabbits during Short Term Exposure to High Altitude (Robert P Tengerdy and Theodore Kramer), 367
  Responses in Mice immunized with Lyophilized Tissues in Freund's Adjuvant Enhancement of Skin Homografts and Dissociation of (J Churna), 175
  Responses Normal, of Bursaless Chickens to a Secondary Antigenic Stimulus (M Elaine Rose and Eva Orlans), 231
Immunity, Cancer and Chemotherapy (edited by Enrico Mihich), *review* by Peter Alexander, 1291
Immunodiffusion Techniques on Cellulose Acetate Simplified Procedure for (J Korn), 1261
Immunological Memory with Anti-lymphocyte Serum Erasure of (Eugene Lance), 557
  Paralysis to Heterologous Tumours Induction of (Nicole Suciu-Foca), 1268
  Response Role of *X*, *Y* and *Z* Cells in (J Halasa), 859
Immunosuppressive Activity of Anti-lymphocyte Sera *In vitro* Detection of (J F Bach and B Antoine), 658
  Effects of Lymphoid Cell Proliferation in Mice receiving Anti-lymphocyte Globulin (A M Denman, Evelyn J Denman and E J Holborow), 177
Implant into Goldfish Telencephalic Parenchyma Regeneration of Peripheral Nerve (Jerald J Bernstein), 183
Impotence Principle in Descriptive Morphology (Bernard Meltzer and Nigel Searle), 1289
Imprinting Drug-produced Isolation and the Sensitive Period (Glenn E Macdonald), 1158
Improved Holographic Model of Temporal Recall (D Gabor), 1288
Inactivation of Isoniazid in Burmese Subjects (S E Smith and Tun Kyi), 1273
Inclusions in Cornubian Granites Petrogenetic Significance of Alkali Felspar Megacrysts and their (B Booth), 1036
Incoming Solar Radiation over the Tropical Pacific (W H Quinn and W V Burt), 149
Incongruent Surfaces in the Human Hip Joint (Peter Bullough, John Goodfellow, Alan Seth Greenwald and John O'Connor), 1290
Increased Receptor Utilization Mechanism of Cocaine Potentiation (K Nakatsu and R J Reuffebsteub), 1276
India, Northward Drift of—Examination of Recent Palaeomagnetic Results (M W McElhinny), 342
Indigofera spicata, a New Hepatotoxic Amino-acid from, Indospicine (M P Hegarty and A W Pound), 354
Indolylacetic Acid (β) on the Growth and the Auxin Catabolism of *Lactobacillus bulgaricus* Effect of (P E Pilet and B Blanc), 285
Indoplanorbis exustus Interaction of Trematodes by Predation within Natural Double Infections in the Host Snail (Donald Heyneman and T Umathevy), 283
Indospicine, a New Hepatotoxic Amino-acid from *Indigofera spicata* (M P Hegarty and A W Pound), 354

- **Induction** of Gibberellin Synthesis in Leaves Red Light (E M Reid, J B Clements and D J Carr), 580
  - of Immunological Paralysis to Heterologous Tumours (Nicole Suciu-Foca), 1268

Libraries, report on scientific, *news*, 216, 217
Ligand of Gandolinium Chelates, Organic Stimulated Emission and Laser Action from the (N Filipescue, C R Hurt and N McAnvoy), 631
Ligands containing Fluoroaromatic Groups (M L N Reddy, M R Wiles and A G Massey), 740
Light and Dark on Secondary Induction of Cornea in Tadpoles of *Rana temporaria* Effect of (V V Popov and D V Popov), 1169
  in this Response Halogen Derivative of 4-Hydroxybenzoic Acid as Root Growth Stimulants and the Importance of (R L Wain, H F Taylor, P Intarakosit and T G D Shannon), 870
  Induced Uptake of Potassium and Chloride by *Chlorella pyrenoidosa* (J Barber), 876
Limestone Calcium Carbonate Content of Karst Water in relation to Flow-through Time (A F Pitty), 939

Limestones Significance of Styolites in Dolomitic (J E Glover), 835
Limpet Biliprotein from the Ova of a Keyhole (W H Bannister, J V Bannister and H Micallef), 754
Limpets Some Aspects of Heart Function in *Patella vulgata* L (H D Jones), 1170
Limulus Discrete Potentials in the Dark-adapted Eye of the Crab (John E Dowling), 28
Linnean Society on Devonian plants, *news*, 126
Lipaemia, Alimentary, in Rats Genetic Influence on (Meyer Friedman and Sanford O Byers), 235
Lipid Films Contact Angles for Thin, and the Determination of London-van der Waals forces (D A Haydon and J L Taylor), 739
  Membranes Action Potentials induced in Biomolecular (Paul Mueller and Donald O Rudin), 713
  peroxides, *news*, 604
Lipids Polymorphism of (Vittorio Luzzati, A Tardieu and T Gulik-Krzywicki), 1028
Lipogenesis in the Rat Effect of Dietary Carbohydrate on Hepatic (E Bailey, C B Taylor and W Bartley), 471
Lipopolysaccharide Pyrogenicity of "Pyromen" (Peter Baume), 970
  Transferases Biochemical Characterization of Mutants of *Salmonella typhimurium* lacking Glucosyl or Galactosyl (M J Osborn), 957
  Transferases Genetics and Cultural Properties of Mutants of *Salmonella typhimurium* lacking in Galactosyl and Glucosyl (R G Wilkinson and B A D Stocker), 955
Liquid Chromatography Chemotaxonomic Studies of Gram Negative Bacteria by Pyrolysis-Gas-Liquid Chromatography (E Reiner and W H Ewing), 191
  Free Surface Existence of a Surface Tension Discontinuity at a (R H J Sellin), 536
Living Cells New Simple Method of Micrurgy on (K W Jeon and I J Lorch), 463
Liver, Chick, lacking in Vitamin B_{12} Effect of Orotic Acid on Activity of Nuclear DNA-dependent RNA Polymerase and Polyribosomal Profiles in Deficient (C M Caldarera, B Barbiroli and M Marchetti), 755
  Effect of Cell Cycle on Recovery from Radiation Damage in the Mouse (J E Coggle), 180
  Mitochondria Effect of Phenylhydrazine and Hydrolysed Glucose Cycloacetoacetate on Adenosine-triphosphatase Activity in (M C Nath, T G Reddi and N Nath), 552
Localization of Tyrosine Hydroxylase Evidence for an Extragranular (Pierre Laduron and Frans Belpaire), 1155
Location of Gamma Globulin in the Endocardium in Rheumatic Heart Disease by the Ferritin-labelled Antibody Technique (R Lannigan and S Zaki), 173
Loci, Homologous, in Two Sibling Species of European Anopheline Mosquitoes Homologous Alkaline Phosphatases and (Umberto Bianchi), 382
Locust Bodywall Activation of Malathion by the (Hafiz Ahmed and B G Gardiner), 776
  Migratory, *Locusta migratoria* L Photoinhibitory Function of the Dorsal Ocelli in the Phototactic Reaction of the (Charles K Barry and Rudol Jander), 675
London flood prevention with barrage, *news*, 799
London-van der Waals forces Contact Angles for Thin Lipid Films and the Determination of (D A Haydon and J L Taylor), 739
London's water examined, board report, *news*, 1202
Long chain molecules, statistical mechanics for, *news*, 126
Longitudinal Spread of pc I Micropulsations in the Magnetosphere (H B Knaflich, J F Kenney and V P Hessler), 1134
Low Oxygen Enhancement Ratios for Radiosensitive Bacterial Strains, and the Probable Interaction of Two Types of Primary Lesion (Tikvah Alper), 862
Low *p*H of Irradiated Sucrose in Induction of Chromosome Aberrations (Muriel V Bradley, Linda L Hall and Sarah J Trebilcock), 1182
  Surface Pressures Circulation within Monolayer Films on Aqueous Substrates at (E R Moss, D M Himmelblau, R S Schechter and R L Pitzer), 349
Lower Dentition of *Kenyapithecus africanus* (L S B Leakey), 827
  Phase Transition in Solid Deuterium Bromide Crystal Structure and the (E Sandor and M W Johnson), 541
LSE proposals for student participation, *news*, 699
Lubricant Failure Role of Austenite and Mineral Oil in (W Grew and A Cameron), 481
Luminescent Properties of Rocks, Meteorites and Natural Glasses under Proton Bombardment (I M Blair and J A Edgington), 157
Lunar Crater Tycho Multiphase Development of the (R G Strom and G Fielder), 611
  Occulation of a Solar Active Region at 4 cm Wavelength (M R Kundu and T Velusamy), 1132
  Society of Birmingham, 200 years (D G King-Hele), *news*, 211
  Surface Metals on the (K H Sun), 243
Lungfish Anti-metabolic Extract from the Brain of *Protopterus aethiopicus* (Henry Swan, Dalton Jenkins and Kerwin Knox), 671
Lymph Node Follicles of Germ-free and Conventional Rats Differences in *Salmonella* Flagella in (J J Miller III and D O Johnson), 1059
Lymphocyte IgG on the Graft versus Host Reaction in F_1 Hybrid Mice Effect of $F(ab^1)_2$ from Rabbit (J D Naysmith and K James), 260
Lymphocytes Observations on the Presence of Titanium and Zinc in Human (Kenneth G Carroll and James L Tullis), 1172
  Radiation Stimulated Incorporation of Thymidine into the DNA of Human (Richard G Evans and Amos Norman), 455
Lymphoid Cell Proliferation in Mice receiving Anti-lymphocyte Globulin Immunosuppressive Effects of (A M Denman, Evelyn J Denman and E J Holborow), 177
Lynch, Henry T Hereditary Factors in Carcinoma, *review* by P C Koller, 199
Lyophilized Tissues in Freund's Adjuvant Enhancement of Skin Homografts and Dissociation of Immune Responses in Mice immunized with (J Churna), 175
Lysine Aminopeptidase by Atopic Allergens Inhibition of Leucine and (L Berrens), 664
  in α-Keratin Further X-ray Evidence of Regularly Distributed (M Spei, G Heidlemann and H Halboth), 247
Lysolecithin on Chinese Hamster Cells *in vitro* Growth-promoting Effect of (Karin Nilausen), 268
Lysosomes Histochemical and Biochemical Study of Synaptic (Mildred K Gordon, Klaus G Bensch, Grace G Deanin and Malcolm W Gordon), 523
  Evidence for a Genetic Relationship between Avidins and (N M Green), 254

Mabbutt, J A *see under* Jennings, J N
Macdonald, Professor George *Obituary* by B B Waddy, 691
Machine tools support by Mintech, *news*, 600
Macromolecules Measurement of Normal Stress Differences in Solutions of (J Harris), 1248
Macrophages *in vitro* Ability of Haemotopoitic Spleen Colonies to form (N Virolainen and V Defendi), 1069
Magic of Numbers, The (K Schiller), *correspondence*, 1084
Magnesium Metals on the Lunar Surface (K H Sun), 243
  on Vagal Inhibition and Acetylcholine Sensitivity of the Mammalian Heart, *in situ* and *in vitro* Effect of Excess (G C Somjen and E N Baskerville), 679
  Oxide-Nickelous Nitrate Cements Mechanism of Bonding in Aqueous (E L Williams and H H Wilson), 548
  with *Escherichia coli* Ribosomes Competitive Binding of Streptomycin and (Yong Sung Choi and Charles W Carr), 557
Magnetic Circular Dichroism and Optical Rotatory Dispersion Measurements Applications of (B Briat and Carl Djerassi), 918
  Faunal Boundaries, *news*, 1097
  Field Evolutionary Processes and Reversals of the Earth's (C G A Harrison), 46
  Field Spiral Structure and Galactic (P A H Seymour), 147
  Resonance and Relaxation (edited by R Blinc), *review* by D T Edmonds, 1080
  Resonance in Biological Systems (edited by A Ehrenberg), *review* by M Ebert and N J F Dodd), 486
  Resonance Proton, and the Helix-Coil Transition (E M Bradbury, C Crane-Robinson, H Goldman and H W E Rattle), 812
  Storms, reconnexion model, *news*, 1099
Magnetite to γ-Fe$_2$O$_3$ Mechanism of Oxidation of (K J Gallagher, W Feitknecht and U Mannweiler), 1118
Magnetosphere Longitudinal Spread of pc I Micropulsations in the (H B Knaflich, J F Kenney and V P Hessler), 1134
  model, *news*, 1099
Magnitude Group Analysis Variance for Earthquake Location and (B A Boult and H Freedman), 47
Maize, Sugar Cane and Tobacco Comparison of the Kinetics of Photosynthetic Carbon Dioxide Fixation in, and its Relation to Photorespiration (A Goldsworthy), 62
Maku, Albumin a New Variant of Human Serum Albumin (L R Weitkamp and N A Chagnon), 759
Malathion by the Locust Bodywall Activation of (Hafiz Ahmed and B G Gardiner), 776
Malformation Cyclopism as a Hereditary (Peter Pfitzer and Horst Muntefering), 1071
Malformations Teratogenic Effects of Hypoglycin-A (T V N Persaud), 471
Malinow, Manuel Rene (editor) Biology of the Howler Monkey, *review* by John Napier, 1082
Malnutrition, FAO/WHO report, *news*, 1094
  Relationship between Total Body and Muscle Respiration Rates in Infants with (B L Nichols, D J Barnes, A Ashworth, G A O Alleyne, C F Hazlewood and J C Waterlow), 475
Mammalian Cells in Culture Nuclear Uptake of Exogenous DNA by (A B Robins and D M Taylor), 1228
  Heart *in situ* and *in vitro* Effect of Excess Magnesium on Vagal Inhibition and Acetylcholine Sensitivity of the (G C Somjen and E N Baskerville), 679
  Somatic Cell Populations Cytogenetic Polymorphism and Evolution in (D T Hughes), 518
Man Histaminase Activities in the Plasma of Subhuman Primates and (John H Peters and Gale R Gordon), 274
Manganese Carbonyl and Carbon Tetrachloride Initiation of Free Radical Polymerization by (C J Bamford and R Denyer), 59
Manning, Aubrey An Introduction to Animal Behaviour, *review* by J D Carthy, 1081
Mare and Ewe pO_2 Levels in the Placental Circulation of the (R S Comline and M Silver), 76
Marine Goby through the Panama Canal Interoceanic Colonization of a (Robert W Rubinoff and Ira Rubinoff), 476
Marine Science, directory, *news*, 598
  sediments, Holocene, meeting, *news*, 802
Marrow Cultures of Human Adults Production of Foetal Haemoglobin in (Judith Goslin Hall and Arno G Motulsky), 569
Marshall, Dr W New director at Harwell, *news*, 497
Marsupial Leucocytes in Culture Chemical Protection against X-irradiation by a New Reducing Agent 1,4-Dithiothreitol in (Y A E Bick and W D Jackson), 479
Marsupialia Prodromus of the Comparative Serology of (J A W Kirsch), 418
Martini, Lucian, and Ganong, William F (editors) Neuroendocrinology, Vol 2, *review* by (K Brown-Grant), 585
Maser Action at 21 Centimetres' Is Interstellar Hydrogen capable of (S H Storer and D W Sciama), 1237
Mass Spectrometer Laser Heating of Coal Particles in the Source of "Time-of-Flight" (W K Joy, W R Ladner and E Pritchard), 640
  Spectrometric Analysis of Oxygen (C E Brion), 946
Massalski, T B *see under* Barrett, Charles S
Mast Cells after Antigenic Stimulation in Adult Rats Proliferation of (John J Miller III and Leonard J Cole), 263
Maternal Plasma, Human, Perfused Placenta and Umbilical Cord Plasma Free Fatty Acid Patterns of (A Robertson, H Sprecher and J Wilcox), 378
Mathematics and the Dainton report, *news*, 897
Maximum-intensity Fluorescence Microscopy (R Barer), 672
Maxwell, Gavin Seals of the World, *review* by L Harrison Matthews, 105
McCrum, N G, Read, B E, and Williams, G Anelastic and Dielectric Effects in Polymeric Solids, *review* by R P Sheldon, 883
Measles vaccination scheme, *news*, 503
Measurement and Significance of Weight Heterogeneity in Some Protein and Polysaccharide Preparations (J Watkins and D E H Tee), 533
  of an Antigen-Antibody Reaction by a Static Method utilizing a Porous Gel (Claude Sculeil and Alfred Nisonoff), 144
  of dT/dΔ (A Douglas and D J Corbishley), 1243
  of Normal Stress Differences in Solutions of Macromolecules (J Harris), 1248
  of the Diffusion Coefficient of Radium A (Otto G Raabe), 1143
Mechanical and Electrical Stimuli Detachment of Sea Anemones by Commensal Hermit Crabs and (D M Ross and L Sutton), 380
  Stimulation Response of Pine Seedlings to (W C Asher), 134
Mechanism of Bonding in Aqueous Nickelous Nitrate-Magnesium Oxide Cements (E L Williams and H H Wilson), 548
  of Closure of the Aortic Valve (B J Bellhouse and F H Bellhouse), 86
  of Olfactory Transduction (Barnett Rosenberg, T N Misra and Robert Switzer), 423, *corrigendum*, 692
  of Oxidation of Magnetite to γ-Fe$_2$O$_3$ (K J Gallagher, W Feitknecht and U Mannweiler), 1118

JANUARY 6, 1968

Anglo-Saxon Problems in Science and Technology

RECEIVED doctrine has it that science and technology are the foundations of prosperity in industrialized societies, which is why it is strange to say the least of it that so little has been heard of this principle in the past few weeks, when what the French call the Anglo-Saxon countries have been trimming their sails to the harsh winds of 1968 What has gone wrong ? How was President Johnson able, on January 1, to outline a programme of financial retrenchment overseas without breathing a word about science and technology ? And where now, in Britain, is all the brave talk about the new opportunities which technology provides ? Only three years ago, Britain, thanks to its new government, was buzzing with talk of how technology would magic away the threat of national bankruptcy More recently, technological strength has been proffered as a means by which Europe as a whole could be welded into a gigantic technological community So, has the British Government lost the faith it once possessed in science and technology ? What else can explain Mr Wedgwood Benn's conspicuous silence in the past few weeks ? And, in any case, what policies towards science and technology should the American and British Governments pursue at a time when both of them are being forced to reduce public expenditure quite drastically ?

The first thing to recognize is the difference between the time scales of change in technical development and in high finance Projects in research and development take years to fructify, but financial crises can blow up in a few months, which is why it is that governments have no choice but to fall back on short-term fiscal measures to deal with situations like those which have arisen in Britain and the United States (which is not to imply that the two crises have more than a few elements in common) But the danger, of course, is that in making plans to deal with immediate problems, governments may jeopardize, perhaps inadvertently, long-term prospects And even if their stop-gap policies do no positive harm, too great a preoccupation with immediate problems may obscure the need for long-term solutions

Ironically enough, this danger may be more immediate in the United States than in Britain The annual round of congressional enquiries into the budgets of the federal agencies has already demonstrated plainly enough that Congress fully shares the Administration's zeal for economies in public spending Indeed, in many ways, Congress is the pacemaker, for it now seems to be accepted that a substantial reduction in the scale of government expenditure in the United States will be a precondition for congressional approval of the tax supplement that the Administration would like to have In practice, the economies which have been imposed in recent weeks in the spending of the federal agencies are real enough, and their effects are certain to be palpable Yet it is sensible enough, for example, that the National Aeronautics and Space Administration should be forced to wait for approval of its plans for the use of the Saturn rocket system in the 70s until there is at least some tangible evidence of how the programme of getting to the Moon will work out

Probably there is also enough slack in the budget of the National Institutes of Health for that buoyant institution to be more or less unaffected in the year immediately ahead To be sure, the National Institutes of Health may find itself having to cut back or to postpone some of its imaginative but ambitious plans for development in higher education, particularly in the training of postgraduates, but that will be just as well at a time when the relationship between American universities and government institutions has not been clarified as much as the circumstances require Ironically, there is much more cause for alarm in the ways in which agencies such as the Department of Defense and the Atomic Energy Commission have been forced to economize in the past year, chiefly because these agencies have been converted almost overnight from fairy godmothers to cheeseparers in their support of basic science and technology in the universities and elsewhere The trouble, of course, is that in spite of the way in which organizations such as the US Office for Naval Research have acted as beneficent and visionary supporters of scientific developments in the United States and elsewhere since the war, and even though the armed services and other mission-oriented agencies profess that basic research is somehow inseparable from their more practical endeavours, the amounts being spent on the support of basic science and technology are necessarily marginal At times of scarcity, it is inevitable that they should also seem expendable The trouble is that a great many institutions elsewhere have become dependent on the services and similar agencies for continuing support These will now inevitably feel the draught All this is understandable enough, but the moral should now be plain A greater proportion of the Federal Government's support for basic research in the universities and elsewhere should in future be undertaken by independent agencies such as the National Science Foundation, even if this should entail a radical revision of the structure of that organization Such a shift of emphasis is, indeed, long overdue, and it will be entirely welcome if the present crisis, with its shortage of funds for research and for junior appointments in the larger universities, provides an incentive towards a policy like this

In Britain, by contrast, the danger that enforced economies will cramp the immediate prosecution of science and technology is less real than the danger that the urgency of the present crisis will compel people to postpone yet again decisions on structural problems which affect the support of science and technology in Britain To be sure, it is too soon to know how seriously the finances of the universities will be affected by the economies yet to come, but it is hard to see that even the strongest pressure from the Treasury will enable the Department of Education and Science to reduce still further the amounts of money available to the University Grants Committee in the five years from this September Most probably the chief result will be to cast down still further those who have been hoping against hope that it might be possible to bring about some revision of the straitened terms of grant for the coming quinquennium But these are temporary measures The real question about the character of research in British universities which needs now to be answered is whether they are to be endowed so generously with funds for research that they can make a continuing and important contribution to the development of science in Britain, or whether that role is gradually to be taken over by other institutions—probably the government establishments There is an uneasy sense that the cumulative effect of the decisions which have been taken about research and development in Britain in the past five years have tended to emphasize the educational function of the universities and to diminish their importance as centres of innovation The difficulty which universities now find of increasing the scale of postgraduate teaching is one symptom of this state of affairs It is hard to believe that it can be in the long-term interests of the British economy

The place of the government research establishments is also central to the problem of how to manage the scientific and technical resources of the British economy for long-term prosperity The present government is temperamentally inclined to take the view that even though many of the establishments have outlived the purposes for which they were first established, they still have a valuable part to play in the advancement of industrial expertise and even, sometimes, in the development of pure science And, of course, there is bound to be some truth in this But the question which must really be tackled directly as a public issue is whether there is not now too great an emphasis on the importance of the government establishments at the expense of institutions elsewhere—the universities and industry

It is improbable that the present balance can be right, for after all it has grown by a succession of historical accidents Most probably the government establishments are at present attempting to do more than is good for them or for the rest of the British economy But it would obviously do more damage than good if the establishments were crudely now to be reduced in scale—what is needed, instead, is a mechanism by means of which their resources can be put more fully at the disposal of the British economy The devices in the Science and Technology Act which permit diversification at the establishments are not sufficient Perhaps the new White Paper which the Ministry of Technology has been advertising will have a better solution to propose

Whistling in the Wind

As good trade unionists know, wage claims at times of economic belt-tightening are no more successful than whistling in a blizzard However sweet the music sounds, it never carries far The Association of University Teachers is far from being a trade union, if it were, it would probably not have persisted with its claim that teachers in universities are underpaid The British Government has rewarded the association for its pains by asking the Prices and Incomes Board, a notoriously unsentimental body, to undertake a survey of university salaries When the association's claims were being rebuffed by the Department of Education and Science and the University Grants Committee, it was possible to feel a fatalistic sort of sympathy—but if the Prices and Incomes Board should conclude that there are no grounds for an increase, that is likely to be an end to the matter And once the board, and its chairman, Mr Aubrey Jones, have the bit between their teeth, no government is going to feel moved to set up a review body more sympathetic to the teachers

The burden of the association's case is that academic salaries have been allowed to fall behind those paid to comparably skilled people in other jobs But who is to know whether or not this has happened because academic jobs are so easy to fill ? The very large numbers of young men and women who want to stay in universities may have so exceeded the number of jobs available that the market price has fallen The teachers' hard-luck story might be more convincing if fewer of their students behaved as if all they want to do is follow them into academic life The point is sharpened if one remembers that universities in Britain have been expanding at a great pace for the past few years, and that the supply of manpower seems to have been no limitation to the process It would be good to be able to say the same for other activities employing highly qualified manpower—the application of computers in industry, for example, is likely to be controlled for some years to come by the supply of systems analysts

It is also quite legitimate to ask why university staff should be paid exactly the same as their opposite numbers in industry If the principle of comparability were applied rigidly, it would lead to absurd situations, and to a society forever fixed in a pecking order established years before This is not the same as arguing that industrialists are in some way more valuable than university teachers—that would be an impossible position to sustain—or that long university holidays and the freedoms of academic life should be paid for by smaller salaries, but that academic qualifications should not be regarded as the passport to a guaranteed income. University teachers, above all, should be aware of this. A degree is not a professional qualification. It does not entitle its holder to membership of a select association whose members are paid the same salary whatever job they do. It might, indeed, be better if there were much greater disparities between the salaries of graduates, particularly newly qualified ones. Not every intending academic can be turned into a systems analyst, but a more significant differential could help the process along.

It is also depressing that the association seems determined to establish standard rates of pay at all British universities. One of the striking developments in education in the United States has been the ability of lesser universities to pull themselves up by their own bootstraps by offering generous rates of pay. The University of Texas, supported by local business, is a good example of this. Are universities in Britain to be denied similar opportunities for self-improvement?

The danger implicit in the association's argument is that, if university teachers are to be paid more, industrial salaries will also increase. And the hard-pressed schools, which can really make out a convincing case for a salary review, would be even less able to attract talented graduates. The next few years, which coincide with the graduation from universities of the children born in the "bulge" years, should offer the schools a real chance to recruit graduates. The universities, with the first major period of expansion after Robbins behind them, are likely to be absorbing fewer of their graduates than they have in the past few years. When all this is taken into account, can the association be said to have presented a convincing case? On past form, Mr Aubrey Jones will be only too eager to decide.

Engineering Compared

THE case for the Common Market has seldom been put more cogently than in the recent OECD report on the engineering industries of member countries (*The Engineering Industries in North America—Europe—Japan*, OECD, 1967, 30*s*.). The United States makes a smaller investment in its engineering industries than does Europe, but produces more than twice as much with almost half the number of employees. In spite of higher wage levels, the United States invested only $4,400 million (at 1958 prices) in 1965 to achieve $162,000 million worth of production. Europe, including the United Kingdom, invested $4,500 million in the same year to achieve an output of $83,000 million. Employment figures in 1965 were 6·7 million in the US and 12 million in Europe. During 1966 productivity in the US engineering industry was $25,000 a head, three times the European average. By contrast, productivity was $10,000 a head in France and Japan, $8,000 in West Germany and $6,100 in Britain.

The OECD report observes that these remarkable differences in efficiency are too important to be explained by a few causes. But it points out that disparities in the size and organization of the market, and hence in the scale and structure of production, are likely to be a dominant factor. The necessary reorganization of production in Europe, the report says, "can be fruitful only if accompanied . . . by effective measures to create a single European market, removing not only the traditional barriers (customs) but also all the other obstacles to trade (i.e. technical and administrative regulations, different legal and fiscal systems, currencies, etc.). In a word, the biggest and most acute problem facing the largest industrial sectors in Europe is the difficulty of surmounting those obstacles which prevent really economic production on a large scale."

The growth of British engineering industry compares unfavourably not only with that of the United States but also with its European competitors. As shown in the table below, its growth during the decade 1955–65 has been less than that of France or Germany and its relative share in the total production of OECD member countries has declined.

DEVELOPMENT OF ENGINEERING INDUSTRIES 1955–65

Country	Per cent increase 1965/1955 (1958 prices)	Per cent share of OECD engineering production		
		1955	1960	1965
United Kingdom	37	11·6	11·2	9·4
Germany	91	8·4	10·3	9·6
France	100	5·1	6·0	5·9
Italy	91	2·1	2·7	2·3
United States	57	61·6	54·7	54·7
Japan	611	2·2	6·1	8·6
Europe OECD	72	34·0	37·4	34·5
Total OECD	73	100	100	100

Diagnoses of what is wrong with British industry are two a penny and about as valuable to a patient who has heard it all before in one form or another. More to the point is what is right with American industry. The OECD report emphasizes the widely known fact that the structure of the United States domestic market favours very large-scale production with consequent maximum returns on capital. Greater profits lead to a higher degree of self-financing than in European companies; in absolute terms, investment is high and equipment is constantly renewed. A further difference is that, whereas in Europe new investment must usually be devoted to replacing capital stock or increasing production on the same technical base, the United States engineering industry can afford to divert the major part of new investment to the less immediately profitable ends of innovation and rationalization. Because plant is being used to its technical maximum, manpower is highly productive. The relatively small number of firms reduces administrative and technical personnel needs, which is a further factor in increasing productivity. Wages, and the standard of living, can be allowed to rise accordingly. All this has long been known in Europe but not, it seems, known well enough.

Academic Issues

THE National Board for Prices and Incomes is becoming a maid of all work for the British Government. The latest commission to land at the board's door is a survey of the pay of academic staff in universities. The government asked the board to take over this task, on a continuing basis, in November, and last week the board issued an invitation for written evidence from interested organizations. The Association of University Teachers, quick off the mark, had submitted evidence before it was asked, and other more slowly moving organizations are certain to follow. The Department of Education and Science, the University Grants Committee and the Committee of Vice-Chancellors and Principals are all likely to respond to the call, in their different ways. Some individuals may also feel impelled to write to the board, and their views, too, will be taken into account, although it would be a pity if the board were slowed down in its work by a mass of memoranda from individuals.

Mr Aubrey Jones; new look at university pay.

The last attempt to adjudicate on university salaries was made by the ill-fated National Incomes Commission in 1963. The commission, cosily called "Nicky" by its friends—and much worse things by the TUC, which refused to co-operate—folded up after the Conservative Government was defeated in the 1964 election. Since then, university pay has been settled by the Government, in collaboration with the University Grants Committee. But academics are always inclined to believe that the UGC is in cahoots with the Government, and the Association of University Teachers appealed for an independent review board. Offered the Prices and Incomes Board, it accepted, without, as it says, "prejudice to the future". The AUT argues that salaries of university teachers are much lower than those of people with equivalent qualifications in other walks of life; since the last review, it says, salaries of university teachers have increased by 5 per cent, while those outside academic life have had rises of up to 20 per cent. It rejects the selfless gestures of some professors who have said that in present economic circumstances university teachers should do without a rise. Professors, it implies, are the last people who should make these gestures, as they are well paid—the great mass of the 15,000 membership of the AUT is less well off. Professors would be the first to complain if the standard of academic work fell because universities could not recruit the best people, it suggests.

The board is not saying when it hopes to finish the survey. But it has a reputation for getting things done, and usually takes about 4–5 months, so there could be concrete results by the middle of this year. Mr Aubrey Jones, chairman of the board, has appointed himself chairman of the team which will investigate university pay. He and another two members of the board team will be assisted by a staff working party consisting of at least another three people, who will be able to call on all the available expertise—economists, statisticians, and the like—employed by the board. In addition, the committee can call on an enquiry team to go out and "ferret out the facts", so there seems no lack of professional zeal in the board's approach to the problem.

Bigger Machine at Weston

THE plan to build a new proton accelerator at Weston, Illinois, seems to be moving vigorously ahead. Among the several innovations which have been made since the decision was taken six months ago to go ahead with the machine is that the University of Toronto has joined the Universities Research Association Inc. This consortium of universities is formally responsible to the US Atomic Energy Commission for the construction and operation of the new accelerator. Forty-eight universities now belong to the consortium. The membership of the University of Toronto will no doubt excite the interest of other universities outside the United States.

The flavour of the Weston Project has changed significantly in the past few months, and particularly since the appointment last summer of Professor Robert Wilson as director of the project. For one thing, the accelerator is now known as the 200–400 GeV machine, which amounts to an explicit recognition that at some stage in the development of the project the energy of the protons which the machine produces will be doubled to 400 GeV.

The possibility that accelerators might be graded is not of course new, but Professor Wilson seems to have hit on a particularly simple and economical way of doing this. To begin with, the machine at Weston will be fitted out with magnets designed to operate at a much higher field intensity than is necessary for the production of protons at 200 GeV. This means that when more money is available, it will be possible to increase the operating power of the magnets, chiefly by adding to the power supply. This is a simpler means of increasing the rating of a proton accelerator than some of the other devices which have been suggested—the addition of extra magnets, for example. All this amounts to a neat exploitation of the fact that in the larger accelerators, the costs of buying land and building a tunnel are a larger proportion of the total, which in turn implies that the costs of magnets are comparatively less important. Professor Wilson seems to have been able to push this balance even further by paying close attention to the design of cheap magnets—this is why it is possible for him to think of building into the new machine magnet capacity that will not be used for some time to come.

IBM Displaced

THE United States Air Force has now chosen to buy computers from Burroughs for the second phase of its programme of automation at its bases around the world. This is a plan to install linked computers in USAF bases to deal with problems of logistics. The contract was originally put out to tender last April, and was won by IBM with a bid of $114 million. Honeywell, which had submitted a bid of only $54 million, complained to the General Accounting Office. As a result of this, the Comptroller-General ordered the cancellation of the IBM contract, despite the Air Force's assertion that price was only one of five factors to be considered, and that only IBM, to use its own words, "satisfied these areas of response". All four manufacturers tendered again, and Burroughs' winning bid was to provide 135 of its "third-generation" B 3500 machines for $60 million.

IBM has confessed itself disappointed by the final decision, claiming the superiority of its products. The USAF, which announced details only of the winning bid on both occasions, seems unrepentant. It has confused a none too lucid issue by saying that the tenders for the second selection "were markedly different from the original submission in terms of capacities, speeds and, in some cases, processing techniques". It also claims that the delay caused by the intervention of the Comptroller-General cost $18 million, so that the American taxpayer need only congratulate himself on a saving of $36 million. Honeywell has pronounced itself satisfied that the original complaint has been shown to have been justified; the exercise seems to have lost Honeywell no favour with the US Government, for the company has just received an order to lease twenty-two computers, worth $8·5 million, to the Department of Defense.

Burroughs had won the contract for the first phase of the same programme, a $24 million order to provide computers for organizing supplies at air force bases, so that the USAF will doubtless find advantages in having standard equipment for base logistics. The first two systems of the second phase will be delivered in March, and two further systems will be installed at Sheppard Air Force Base, Texas, in April and May. These will be used for training. A test programme will begin at Langley Air Force Base, Virginia, in September and, if the results of this are satisfactory, the computers will be installed at bases around the world during 1969 and the first half of 1970.

Supersonic Plans

THE introduction of supersonic transport aircraft is bound to increase problems of air transport control and flight planning. As well as flying three times as fast as aircraft now in service, supersonic aircraft will fly much higher, at between 16 and 21 kilometres. Meteorologists, familiar with the problems of long-range forecasting, are already beginning to wonder how the supersonics are going to affect them. Some results of this process of looking ahead have now appeared in the form of a report from the World Meteorological Organization called *Meteorological Problems in the Design and Operation of Supersonic Aircraft*. The report is written by R. F. Jones, R. M. McInturff and S. Teweles.

The difficulties of the sonic boom are already familiar enough. As well as the regular boom which the aircraft makes, the report discusses the phenomenon of "superboom", which is thought to be caused by the simultaneous arrival at the observation point of shock waves from two distinct parts of the flight path. Overpressures as great as 3·6 mbar have been recorded in low level tests, nearly five times as great as the nominal overpressures which the SSTs are expected to produce. It may be possible to eliminate superbooms by avoiding turning manoeuvres or supersonic acceleration in level flight, but atmospheric turbulence may affect the issue by producing quite rapid accelerations and changes in aircraft attitude. Actual experience with the first supersonic airliners will be needed before the position is clear.

The actual incidence of the boom may also be affected by unscheduled changes of flight plan. The thrust of a jet engine decreases with increasing temperature—BOAC, for example, has estimated that a five-degree increase in temperature produces a 25 per cent deterioration in acceleration between Mach 1·1 and 2·0. And because the SSTs will fly much higher than existing aircraft, information about temperatures is relatively more scarce. Most of the handicap of higher temperatures is experienced in the trans-sonic phase of the flight, between Mach 0·8 and 1·2.

The problems of turbulence, and its effects on aircraft, are not well understood. One problem, as the report explains, is that aircraft in flight filter from the whole spectrum of turbulence those frequencies to which they are most susceptible. Thus results with one aircraft may not be duplicated with another. Short wavelength disturbances may affect the fatigue life of the aircraft without actually making passengers feel uncomfortable, while long wavelengths may move the aircraft bodily but smoothly, without imposing great strains on its structure. Between these two extremes there are wavelengths which cause the aircraft to roll or pitch. Some turbulence is associated with cloud structures, and may be possible to avoid, because heavy cloud formations can be detected by radar. Clear air turbulence is a more severe problem, and there is evidence that it will be experienced at SST cruising heights. In flight, warning devices may help, but only if they can detect CAT 100 miles ahead of the aircraft.

There will also be a danger of large doses of radiation, because at supersonic aircraft heights the atmosphere will be too rarefied to provide a protective screen. The report confirms the suggestion that galactic cosmic rays, a continuous background through which the SSTs will have to fly, will not be a hazard. But there does seem to be a danger if exceptional solar events such as solar flares are ignored. The report contains a calculation by M. Haurwitz, previously unpublished, which shows that for a hypothetical event of the magnitude of the event on November 12, 1960, passengers on a three hour flight at 21 km would receive a dose of radiation twice as large as that recommended for a whole year. Warning devices in the aircraft, and careful preflight planning, will be necessary to minimize the dangers. Another hazard is the presence of ozone in the atmosphere; even small concentrations are poisonous, and it is thought that concentrations of more than 0·1 ppm by volume could not long be tolerated in the aircraft Concentrations of this order are common at 15 to 18 km, and may occasionally be ten to fifty times as great; at 21 km a value 100 times the danger level may be encountered. Fortunately, ozone is easily removed by filters, which will be fitted to the aircraft.

Rain and hail are less easy to deal with Hailstones, the report says, constitute one of the greatest dangers to supersonic flight For this reason, it will be vital to avoid penetrating cumulo-nimbus cloud at cruising speed, and detection by airborne radar will be provided But a supersonic aircraft takes 100 miles to change course by 90°, so the equipment will have to be reliable, and carefully watched

Industrial Oceanography

A NUMBER of French industrial companies have formed a scientific and technical association for the exploration of the oceans, ASTEO The association had its origin in a project of the development council of Aquitaine to establish a regional bureau of marine engineering It was soon realized, however, that the task of co-ordinating the large number of industries and scientific techniques would require a national organization The members of the new association, therefore, are companies from all over France, but the association's headquarters will be in Bordeaux Naturally enough, several shipyards belong to the association, and two of the biggest French shipping companies, Messageries Maritimes and the Compagnie Générale Transatlantique, are also among the founder members But there are a number of firms on this list with relatively few nautical associations Hispano and SCNEMA, Nord-Aviation, Dassault and Sud-Aviation, the Compagne Générale d'Electricité, and SEREB (Société pour l'Etude et la Réalisation des Engins Ballistics), whose director-general, M Charles Cristofini, will be the first president of the association

Among the first aims of the association will be to review the possibilities for French industry in oceanography. It is also hoped to establish an information centre which would use the computers of the SEREB at Bordeaux or the Compagnie Générale d'Electricité at Marcoussis M Cristofini has taken care to emphasize that the association is in no way a competitor of the National Centre for the Exploration of the Oceans Rather, the new association, some of whose members are also members of CNEXO, will complement the older organization

In Britain the participation of diverse industries in oceanography is rather less formally ordered This may be partly because certain large British companies active in oceanographical research, such as Hawker Siddeley and Vickers, have many subsidiaries or associates specializing in the techniques involved in this kind of work Co-operation is within the company rather than between companies But it is interesting to note that the British Aircraft Corporation has been working with Imperial College, and with the assistance of the Bristol shipyard of Charles Hill, and Normalair Ltd, on the development of an underwater house (Project Kraken) The Kraken house would be situated a hundred feet below the surface, and would allow divers to work at depth without having to undergo decompression The Guided Weapons Division of BAC will be investigating the type of structure needed for the Kraken house, and working on the features necessary to support life This is the first submarine excursion of this kind by BAC, though the Guided Weapons Division played a small part in the British Polaris programme

The general objectives for Kraken—named after Tennyson's sea-monster—have been laid down by the Imperial College team led by Brian Ray These are for a house capable of providing life support to a 4-man research team living at depths of 80–100 ft for 2–3 weeks or more There would also be an ample margin for visitors on shorter missions This range lies just within the working range of the atmospheric gases Most of the work on saturation dives (in France and the United States) has concentrated on greater depths and on oxyhelium saturation Remarkably little is known about the effects of prolonged saturation with air under pressure Thus a prime objective of the experiment is to gather physiological data on air saturation diving The chosen depth range is practical in a number of ways The cheap gas and modest depth will keep down running costs Much of Britain's continental shelf is within range for 100 foot diving platforms

By living at depth much more work can be done than from surface dives, each one of which must be followed by lengthy decompression Kraken's promoters believe that the practical value of the house will lie in the commercial fields of prospecting, of surveying and for research in support of fish farming

The quarters that BAC has designed round these objectives are a structure rather like a railway coach divided in two internally. The all-purpose living area will be 14 foot long and permanently heated by a system of hot water circulating in pipes The 10 foot work area will not be heated There is no need for a pressure vessel hull since pressure inside and outside Kraken will be at equilibrium (varying a little with the rise and fall of the tide) The house will be permanently open to the sea through a hole in the bottom Gas and power will be piped from the surface The only thing still lacking is the money to build the operational house for next summer

More Social Science

TOTAL research and development expenditure in the United States during 1968 will reach $26,500m—an increase of over $700m or of 3 3 per cent compared with the estimated expenditure for 1967 This is the New Year message from the Battelle Memorial Institute, whose last year's prediction for the 1967 expenditure was in fact 8 per cent below the current estimate

The Federal Government is the largest contributor to research and development expenditure, and during 1968 is expected to provide $17,200m, an increase of 2 2 per cent on its support last year Industry will spend $8,300m, an increase of 4 8 per cent, and the colleges and universities about $865 million, which at 8 8 per cent is the largest proportionate increase on last year's figures The remainder of 1968 spending is made up by the $265 million which will be provided by other non-profitmaking institutions The Battelle Institute points out that although the Federal Government is the major source of research funds, accounting for 65 per cent of the total, 69 per cent of all research is in fact carried out in industry. These figures take account of the reduction in Federal research funds voted by Congress last month (*Nature*, **216**, 1155, 1967).

Analysis of 1968 expenditure shows a relative shift to the social sciences in the distribution of Federal research funds. For the first time since figures became available, the increase in Federal spending in this sector will be greater than the increase in the physical sciences. Research into social problems is a dominant factor in the programmes administered by the Department of Health, Education and Welfare (HEW), the Department of Housing and Urban Development (HUD), the Department of Labor and the Office of Economic Opportunity (OEO). The 1968 fiscal year budgets for these departments are 220 per cent higher than those for comparable programmes in 1961. In contrast the spending on research and development by the Department of Defense, NASA and AEC has increased by only 73 per cent during this period, most of which is a result of the substantial rise in space expenditure. Nevertheless, these three agencies will receive 86 per cent of Federal research funds in 1968, as distinct from their 91 per cent share in 1961.

In the decade 1955–65, research and development expenditure grew at an annual rate of 14 per cent, against an annual growth rate of 5·5 per cent in gross national product. The Battelle Institute feels that this runaway rate of growth has now been contained and will remain so for the foreseeable future. Henceforth research and development is likely to grow at about the same rate as the GNP. Budget administrators in other countries who have watched with alarm the importunate demands of science research will take cheer from the *modus vivendi* now apparently reached in the United States. Scientists may feel differently.

Teaching Aids in Sussex

A GRANT of £10,000 has been awarded by the Department of Education and Science to the Centre for Academic Services at the University of Sussex to assist a co-operative project for the development and application of educational technology at all levels of education in the region. The centre at Sussex is one of the ten which were selected by the University Grants Committee to develop audio-visual aids in education. It was founded in February 1966 with the help of a grant from the Rank Organization.

This particular study will be carried out in association with the Nuffield Resources for Learning Project and the five local education authorities of East Sussex, West Sussex, Brighton, Eastbourne and Hastings. The objective is to analyse the existing audio-visual resources in schools and to estimate the potential for educational technology in the area. Regional co-operation in developing new methods and equipment will be considered and the costs and possible effects of such developments will be analysed. The proposals for joint activity include programmed learning, radio, closed circuit and broadcast television, language laboratories and film and projection systems.

A policy committee has been set up by the university to advise on the project and includes the five chief education officers of Sussex, Mr R. H. Adams (divisional inspector of schools for the south-east of England), Mr Tim McMullen (co-ordinating director of the Nuffield Resources for Learning Project), Professor G. Allen (sub-dean of the University School of Educational Studies), and Mr Norman Mackenzie and Mr Hywel C. Jones (director and deputy director of the Centre for Academic Services), the university will act as co-ordinator for the scheme. The project was started on November 1, 1967, and is expected to last for two or three years.

What is interesting about the scheme is that it involves the getting together of five local education authorities with the university, to their mutual advantage. According to Mr Norman Mackenzie, although the operation is a modest one it will at least show how advantageous such co-operation can be.

Training Computer Users

THE Government and industry are well aware of the need for trained computer manpower and of the shortage of suitable training courses for such personnel. To help satisfy this demand, the British Computer Society is introducing professional qualifications this year. And training courses for computer users, particularly those on the professional and managerial side, are also important. It is therefore welcome that new and extended computer courses are being made available, from the end of January, to people in just this group by Rolls-Royce Ltd.

Rolls-Royce has for many years organized a wide range of courses of various levels in computing and data processing for its own staff. The Ministry of Technology seems to have suggested that the firm's courses should be extended to people from other firms. The suggestion was accepted and the courses now offered have been designed to make them acceptable to people from a broad range of other organizations.

Five-day residential courses in computer systems in management design, research and development will be held in Nottingham at a cost of 150 guineas each (one guinea = £1·05). One-day appreciation courses for executives for 25 guineas will be held in Manchester and London. Four-week courses in systems analysis and design will be held in Largs, Stratford upon Avon, Derby and Droitwich. In addition there will be three short courses for directors of firms with a turnover of £50 million and above. The value of these new courses may lie in the wide experience of Rolls-Royce in specific applications of computers.

New Look Laboratories

THE 39th Building Bulletin of the Department of Education and Science (HMSO, 13*s* 6*d*) deals with the design of a science block for a large boys' grammar school. The block was designed for the Oxford School—a new school formed by the merger of the old-established City of Oxford High School and the prewar Southfields School. Four architects and a quantity surveyor of the Development Group of the Architects and Building Branch at the ministry worked on the project in collaboration with the Oxford local authority. Two consulting firms were called in to advise on heating and electrical work, and the school was built in just over a year and a half.

The importance of science in the curriculum seems to have been fully appreciated from the beginning, partly on the basis of the 1961 policy statements of the Science Masters' Association (SMA) and the Association of Women Science Teachers (AWST) (now merged into the Association for Science Education) Accommodation in the Oxford School was therefore provided for each of the three stages of science education in secondary schools described by the SMA and the AWST statements—two years of general science teaching in the introductory phase, three years of intermediate work leading to O-level and two or three years of advanced work The Oxford School has a four form entry, and a total of about 800 boys Allowance was made for six teaching periods a week of science in the introductory phase, three to four periods for each of chemistry, physics and biology in the middle school and seven periods for each of the three subjects in the sixth form The proportion of time allotted to science under this scheme is higher than in most other schools, with the result that the science block is larger than is usual Twenty-four boys per class was thought to be the best number for middle school science, so that flexibility can be maintained in the timetable, while fifteen was considered the optimum number for experimental work in the advanced stage Mathematics classrooms have added to the size of the block

Self-contained subject departments were provided for the school, following the wishes of the staff, but the bulletin suggests that better use might have been made of space if closer integration had been considered, particularly as the boundaries between science subjects are becoming more blurred Stores and preparation rooms for different subjects which often provide similar facilities and apparatus could well be shared by laboratories of different disciplines The design of the separate departments is described in detail in the bulletin

As well as educational questions the group had definite technical objectives in view The first was to test a dimensional control system proposed by Dr J W Harding of the Building Research Station in his paper "Co-ordination by Design Modules" The second was to develop a rapidly erected "dry" form of construction that can be used for a variety of ten-storey buildings Further use of the lighting system PSALI (permanent supplementary artificial lighting of interiors), first applied by the group to rooms at Harris College, Preston, was the third objective This system is designed to provide strong light during the day to compensate for lack of daylight, but at night provides a lower level of light throughout the room The fourth intention of the group was to gain experience with a computer for processing the bill of quantities, and apply modern management techniques, such as network analysis, to the scheme

The project was under way before even the preliminary conclusions of the Nuffield Science Teaching Project were published, and the bulletin admits that the Oxford block may not be the best answer for the Nuffield requirements, but the detail and ideas put forward in the bulletin will be of considerable value to those designing science buildings in schools.

Advice from Harwell

DESPITE the admonitions of the Select Committee on Science and Technology, Harwell continues to diversify This time it will be lending its experience to engineering companies involved in the problems of heat transfer and fluid flow In return for an annual fee of about £1,000, firms will receive reports on the design of equipment, and there will also be a consultation service available to individual firms The Chemical Engineering and Process Division has for the last ten years been working on heat transfer and fluid flow in the design of nuclear plants, and has therefore come into repeated contact with many of the firms that have shown interest in the new service As early as 1954, for example, APV collaborated with Harwell on the flow of thorium bismuthide through pipes This history of co-operation doubtless explains the enthusiasm felt in industry for the new service The Atomic Energy Authority has announced that there will be long-term support programmes of research into problems chosen in consultation with industry

Perhaps about 10 per cent of Harwell's scientists are now engaged on projects which could be described, in the words of the select committee, as "not inextricably linked to the primary task" of the Atomic Energy Authority Finding ways of filling in the spare time of vast nuclear establishments is not merely a British pastime At Oak Ridge Laboratory, in the United States, for example, there are teams working on desalination and centrifuges for medical use, both areas already tackled at Harwell

Britain Sick

AMONG the winter "epidemics" which have recently been spreading through Britain, influenza at least seems to be on the decline But bronchial complications associated with the infection are still increasing and the red warning for extra available hospital beds is still on

The virus which has been causing this latest outbreak is influenza virus *A*2, which is very similar to that responsible for the pandemic in 1957 and for several outbreaks since then Of the three types of influenza virus, *A*, *B* and *C*, type *A* is the most common cause of influenza in humans and is associated with the pandemics and serious epidemics, while type *B* is usually associated with small outbreaks which are rarely extensive, type *C* usually causes inapparent infections Because the virus is not a new sub-type, it is thought that most people will have acquired immunity to infection, and that the existing vaccines which consist of recent strains of *A*2 are likely to afford protection The principal danger arises when one sub-type mutates to another as in the pandemics of 1891, 1918 and 1957 and the serious epidemics of 1946 The periodicity of outbreaks on a less extensive scale is usually related to the accumulation of susceptible individuals and the removal of immune ones by death

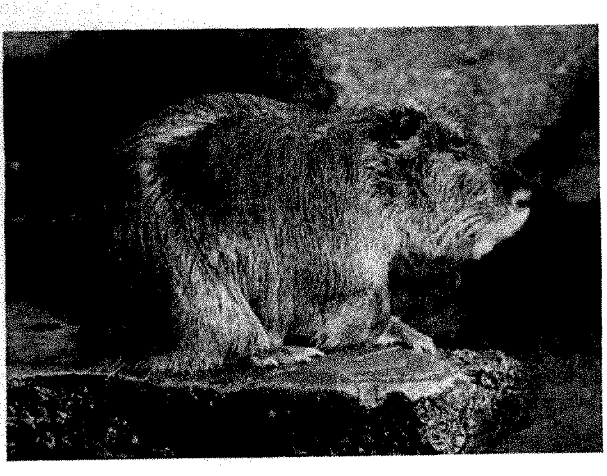
Another RNA virus—respiratory syncytial (chimpanzee coryza agent)—has been identified as the cause of death of five infants in Walsall and two more infants have recently been admitted to hospital with the same infection This virus, which usually causes minor respiratory infections in adults, may, however, be associated with bronchitis and broncho-pneumonia in children and is very widespread—infecting children within the first few months after birth Furthermore, antibodies present in the serum do not always prevent re-infection. According to Dr H. G. Pereira of the National Institute for Medical Research, the prospects of an efficient killed vaccine are not very good and a lot of work remains to be done in developing an attenuated virus vaccine.

Thirteen babies have so far died from a bacterial infection, gastro-enteritis, caused by *E. coli* strain 0–128. Happily, there have been no new cases within the last few days. It now seems that the infection was not the sole cause of death in every case. The involvement of multiple drug resistance transfer is the most likely explanation of how the bacteria became resistant to eight of the eleven antibiotics which have been tested at the Middlesbrough laboratory. The extrachromosomal element, *R* factor, which is responsible for infectious drug resistance is transmitted by conjugation from a resistant bacterium, through a pilus to a sensitive strain which also becomes resistant. The transfer process is repeated from cell to cell and the normal process of cell division also contributes to the rate of spread of multiple resistance in a susceptible population. There has been a suggestion that a combination of drugs might be effective in combating the infection, but this has only been shown experimentally, and *in vivo* applications would not necessarily be successful because the pattern of resistance in different individuals varies. Adults do not seem to be similarly infected; they have probably developed resistance.

Although the strain of *Salmonella* causing typhoid in the borough of Ealing has not yet been named, the same strain has been isolated from three cases. So far, typhoid has been confirmed in two patients, and four people have given positive specimens but have no symptoms. A spokesman at the Ealing Health Department said it was difficult to identify the original carrier of the infection.

Mink in the Wild

WILD populations of mink and coypu, descended from animals which have escaped from fur farms, have been established in England for some years. In spite of vigorous eradication campaigns, the animals are still so numerous that the Ministry of Agriculture has now had extended for five years the legislation whereby occupiers of agricultural land are obliged to report sightings to the ministry. The regulations which govern the keeping and transporting of the animals also remain in force.



Coypu: 136,000 killed in three years.

Coypus closely resemble beavers in appearance. Originally native to South America, they have been established in Suffolk and Norfolk since 1939. The damage they caused was largely compensated by their activity in keeping dykes and waterways free of weeds, and as long as they were worth trapping for their pelts their numbers remained within reasonable limits. But when coypu fur dropped out of fashion the population burgeoned and the damage done to crops such as sugar beet and by the burrows made in river banks reached significant proportions.

A thousand mink are trapped each year.

In 1962 a campaign was mounted to restrict coypus to a few sanctuaries in the Norfolk Broads, and by 1965 136,000 animals had been killed.

Dr R. M. Newson of the Ministry of Agriculture's Infestation Control Laboratory estimates that the survivors of the campaign now number about 5,000. Although a population of this order may be relatively harmless, rigorous control measures are still necessary because of the potential damage which could be caused by another population explosion. Not only have coypus developed a propensity for sugar beet over their usual diet of roots and weeds, but the undermining of dykes by their burrows, combined with high floods, could cause inestimable havoc. The population of wild mink has increased more slowly than that of coypu. Mink are members of the stoat and weasel family and are native to North America. Wild mink have been established for some time and about 1,000 are trapped alive each year.

There appears to be room for disagreement on the precise amount of damage that mink do. The Ministry of Agriculture believes that wild mink are a potentially serious pest to fish, wild birds and poultry. Fur-breeding experts, however, consider that frogs, mice and other economically worthless animals form the major part of their diet, and that mink may often be blamed for the depredations of other animals such as ferrets. But the Ministry is sufficiently convinced to have set up some 2,000 traps throughout the country. Mink fur, of course, still commands a considerable price on the fashion market. There are now 330 mink farms in England which export about £1 million worth of pelts a year. An average pelt sells for £10, and about 70 pelts may be needed to make a coat. The young are born in March at an average of five to a litter; raised on a diet of lights and offal, they are ready for pelting in November. For those with a feel for mink, the farming can be a profitable business.

Help for the Tropics

An appeal for £2 million has been launched by the United Kingdom Foundation for the International College of Tropical Medicine. This foundation, an entirely independent and academic organization—the conception of Mr Geoffrey Myres, a New Zealand surgeon with wide experience in the tropics—has been set up to serve the cause of medicine in tropical and subtropical countries.

The international college aims to help countries in which the shortage of doctors, nurses and other medical staff is acute, by establishing postgraduate tropical medical centres. At the moment, postgraduate tropical medicine training is only available outside the tropics as, for example, at the schools of tropical medicine in Britain. The centres envisaged by the foundation will comprise a hospital for training in clinical tropical medicine at postgraduate level, a school of tropical, social and preventive medicine and a research institute. Under the constitution of the college, it will be able to organize study and correspondence courses, conduct examinations and disseminate information through journals, textbooks, visual aids and libraries.

A positive step has already been made by the donation of land by the government of Uganda for the establishment of the first centre. Two other tropical countries have also offered land. It is hoped to establish other centres in Asia and Latin America. Specialists in tropical medicine from 15 countries form the advisory council, under the presidency of Professor T. A. Lambo, dean of the Medical Faculty, University of Ibadan. The council is backed by a separate board of trustees to manage financial affairs, and by an executive office with a provost to administer the college on behalf of the board and council. Charitable foundations are being established in several countries. The United Kingdom appeal, the first to be made, aims to raise enough money to enable the college to realize its objectives, and in particular to meet the capital expenses of the establishment and running costs of the first centre. Prominent people from the medical, scientific and other professions and industrial and business life are included in the membership of the UK council and executive committee.

Bringing Gas Ashore

Nobody yet knows what natural gas in Britain will cost. Despite this, the Gas Council aims to supply natural gas to all area boards by 1970, and the total expenditure on transmission and distribution over the next five years will be about £800 million. The first of the new pipelines, from Easington in Yorkshire, where gas comes ashore from the West Sole field of the British Petroleum Company, is already transmitting gas. Since July 1967, it has been feeding an average of 100 million cubic feet of natural gas a day into the national transmission system. Details have now been released of a new gas terminal now under construction at Bacton on the Norfolk coast. Initial supplies will go into the Gas Council's No. 2 feeder main, now almost complete.

The council aims for a huge capacity for this terminal, the first part of which is expected to be in operation by the middle of 1968. It is intended to have a maximum capacity of 4,000 million cubic feet of natural gas a day, nearly four times as much gas as is currently used throughout the whole country. The terminal will eventually handle natural gas from the 3 major fields discovered off the Norfolk coast—the Leman and Indefatigable fields which the Shell–Esso Group and Gas Council–Amoco Group share, and the Hewett Bank field, shared by the Arpet and Phillips Groups. Facilities being constructed for the Gas Council are for the reception of the gas and its distribution. Among the principal processes will be filtering of the gas, check-metering if required, heating, blending, odorizing and methanol injection.

A group of architects has been appointed for the design of the terminal, and most of the contracts awarded. The clients are taking due notice of the need for proper landscaping; the basic design for the Gas Council and Shell–Esso, which includes tree planting and grassed earth, has been agreed with the Royal Fine Art Commission. Clearly the hope is that in the rush to get natural gas to the public within the framework of the present economic restrictions, the amenities of the Norfolk coastline will not be sacrificed in aid of progress.

Hydraulics

The Ministry of Technology's Hydraulics Research Station, at Wallingford, Berkshire, has two main functions—to investigate specific problems in the field of civil engineering hydraulics for organizations both in the United Kingdom and overseas, and to conduct research in support of this work. The station's activities in 1966 are recorded in its annual report, just published (HMSO, 11*s*.). Services of the station are provided on a non-profit repayment basis and they appear to be much in demand; 140 investigations were in progress during the year.

One interesting project involves the possible use of synthetic seaweed as an aid in building up beaches. The station is trying to find out whether this material will promote onshore transport of sand and, if so, by what mechanism. Using a special polypropylene of normal density but modified elasticity, a model seaweed bed was laid offshore from a beach in a wave flume. The scale of the model was 1 : 10, and coal particles were used as the bed material. In such a flume, beach changes could only result from changes in onshore–offshore transport. Accumulation on the beach necessarily implied that sediment had come in from offshore, in contrast to the situation on a real beach where accumulation can be caused by changes in littoral drift. With the seaweed in position, the sea-bed eroded offshore and build-up of the beach occurred. Measurements were carried out to find a possible explanation for this. Full-scale tests were made at an offshore synthetic seaweed installation at Bourne-mouth, and confirmed the laboratory tests, although some improvements in the anchoring of the synthetic fibre "pony-tails" were made

Several overseas projects are being investigated One of the most important must be the construction of two major dams on the Orange River, South Africa, as part of the large scheme to provide hydro-electric power and water for irrigation The station has continued and extended its tests on models of the Van der Kloof and the Hendrik Verwoerd dams Work on the Van der Kloof dam now includes investigations into erosion of the river bed some 500 ft downstream of the dam face The aim of tests is to find the most satisfactory method of armouring the alluvium in order to prevent exposure of the shale, and to determine the minimum size of armouring material required and, if possible, to demonstrate a practical method of placing the armouring The report also discusses an analysis being made of the benefits the station brings to the economy and quotes examples based on investigations completed during recent years Initial capital savings of approximately £1 25 million have been reported in connexion with construction of three new bridges for motorway and trunk-road crossings of riverflood plains, and a saving of £2 million resulted from a decision not to build a proposed new training wall for the entrance to a port after it was found that it would not produce the improvements required The saving of £3 25 million on these four projects, the report says, has more than paid the whole cost to public funds of setting up and running the laboratory

Receipts for 1966 totalled over £300,000 The cost of running the laboratory was £482,000 inclusive of interest on capital employed and depreciation of buildings and plant.

More Reliable Pesticides

A RECENT report by the World Health Organization (*Specifications for Pesticides*, WHO, £2) continues the work, begun in 1953, of specifying the quality control procedures for assessing the condition of pesticides The present volume includes specifications for all pesticides currently in widespread use in public health programmes

Pesticides are liable to deteriorate during transit and storage, especially in the harsh conditions of the areas where they are most used Not only the active ingredient itself but the physical properties of the pesticide, such as its suspensibility in water, may also be impaired The specifications drawn up by the WHO Expert Committee enable users and manufacturers to test the quality and durability of commercial pesticides

As the report points out, the standards to which a pesticide is produced are a compromise between what the manufacturer can make, what the user wants, and what he is prepared to pay for it It is therefore necessary that both manufacturer and user know for what purpose a pesticide is required, how it is to be used and what abnormal conditions of storage may have to be met

Estimates that up to a third of world food production is destroyed by pests, and mounting evidence of the damage that can be caused by the unselective application of pesticides, are compelling motives for a more precisely controlled use of toxic chemicals The WHO report is a valuable step in this direction

European Biologists

BIOLOGY is a very diverse and all-embracing subject and the task of establishing "equivalences" for university teaching is by no means easy Indeed, the question arises as to whether it is really necessary for higher education to be systematically organized A new report, *How to Qualify as a "Biologist" in the Universities of Europe*, by Jean Leclercq, professor of zoology at the Faculty of Agronomic Sciences, Gembloux, examines this problem The report, which deals with the teaching of zoology and general biology at university level, is one of a series of publications called "Education in Europe" and published by the Council for Cultural Co-operation of the Council of Europe

Of the eight European countries which Professor Leclercq has examined, Britain, he says, has the greatest academic freedom The system in Belgium, on the other hand, is one of the most rigid operating in Europe and a great deal of importance is attached to the exact sciences—physics, chemistry, calculus and so on—in the basic training of biologists Belgian teaching staff in universities and institutions possessing university status do, however, have complete control over the content of the courses The situation in France is quite the reverse—the system seems to be less rigid but French teachers have less real freedom than their Belgian colleagues There exists a Franco-Belgian cultural agreement, the object of which is to encourage future Belgian students with the qualifying diploma in science to proceed to the second-stage course in a French university or, alternatively, to permit French students with a certificate attesting that they have passed the qualifying examination for higher studies (SPCN) to proceed to take their *licence* in a Belgian university In general, however, this equivalence agreement has produced disappointing results

University entrance from the senior forms of secondary schools into universities in the Federal Republic of Germany is a fairly easy process and both the *Diplom* and *Staatsexamen* courses take five to seven years On paper the German student is entirely free to choose the lecture-series which he wants to attend and, subject to certain restrictions, to draw up his own programme of work considerable academic freedom also exists for the teachers But, according to Professor Leclercq, the German system is ill-designed for the establishing of equivalences and needs to be thoroughly remodelled.

In the Scandinavian countries the university curriculum resembles the studies systems in the universities of Germany and Britain and there is considerable academic freedom The selection process for would-be biologists is very stiff and the number of young Finns hoping to go to university is very large The syllabus for the first two years of the bachelor (FK) can be compared with that of the ordinary *licence* course in France, Belgium and other countries

As Professor Leclercq points out in his general conclusions, "biology studies as carried out in the universities of eight European countries have precious few common characteristics" But he feels that the difficulty of defining equivalences should not prevent students from transferring from one system to another

NEWS AND VIEWS

What are X-Ray Stars?

It is only a few years since rocket flights from North America unexpectedly revealed the presence of discrete sources of X-ray emission in the sky, but the consequences have already been quite considerable. The mere handful of recognizable sources has grown to more than thirty, and there is every prospect that the programmes of rocket exploration planned by several groups in the years ahead will identify many more of them. Already, however, it seems very much as if the known X-ray sources differ from each other in important ways. The source referred to by Dr P. J. Edwards on page 43 of this issue has been observed independently by groups from Australia, Britain and the United States, and is distinguished by the rapidity with which its intensity has changed. Between April 1967, when the first observations were made, and the early autumn last year, the intensity of this source had decreased by a factor of sixty. It is good to see that Dr Edwards has been able to put some flesh on the familiar skeleton of the notion that Centaurus *XR*2 is a nova, but there is probably still some chance that events will bear out one or more of the other theories in the field—for example, that X-ray stars are binary systems able to accrete gas or plasma and which may also be self eclipsing. And clearly, as the work of the Berkeley group reported on page 32 makes plain, there is likely to be continuing interest in the years ahead in the general background of X-ray radiation.

Whether the recent work on the X-ray source called Cygnus *X*2 will simplify these issues it is too soon to tell. Some months ago a group at the California Institute of Technology was able tentatively to identify the X-ray source with a visible star (*Astrophysical Journal Letters*, **148**, 129, 1967). Now it has turned out that the visible star is in fact a double system. Writing in the *Astrophysical Journal Letters* (**150**, 95, 1967) Dr E. M. Burbidge and her colleagues have compared the variations of the Doppler displacement of spectral lines at intervals of a few days, and have found that the observed variations are most easily explained by supposing that the stars concerned are moving in closed orbits at about 250 km a second, which implies an orbital period of a day or so for stars which are as massive as the Sun. Dr Allan Sandage and his colleagues at the California Institute of Technology cap this tale in the same journal (page 99) by describing fluctuations of the optical intensity of the same source which are measured on a time scale of only minutes, and they conclude that the double system responsible for their observations is likely to consist of two roughly comparable stars separated by a distance which is likely to be a fraction of an astronomical unit—a mere million miles or so for stars which are comparable in mass with the Sun. Those who know about the stability of stellar structures will probably have plenty to say about this model. It is, of course, too soon to know how widely applicable it can be.

The Truth about Stacking

from our Molecular Biology Correspondent

Perhaps the most interesting turn taken in recent years by polynucleotide chemistry has arisen out of the discovery that single-stranded polymers such as poly A are not simply random coils in neutral solution. The observation of spectroscopic effects, implicitly associated with defined stereochemistry—hypochromicity, large and characteristic Cotton effects in optical rotatory dispersion or circular dichroism—led to the view that the bases were to a large extent stacked on one another, and it was widely speculated that in the limit of full stacking, the chain would possess the conformation of one strand of the double-helix of a fully base-paired nucleic acid. However, a physical basis for stacking interactions was lacking, for no clear hydrodynamic evidence was available to demonstrate the physical existence of fixed steric relationships between bases. In the absence of such data, the interpretation of the optical phenomena amounted only to a rational guess. The deficiency has now been made good by an elegant piece of physical chemistry by Eisenberg and Felsenfeld (*J. Mol. Biol.*, **30**, 17; 1967).

Neutral poly A was used, and a series of fractions of narrow molecular weight distribution were prepared. The work rests on the discovery that conditions of salt concentration and temperature could be found under which the polymer behaved ideally; this is at the Θ, or Flory, temperature, where interactions between polymer molecules, between polymer and solvent and between different segments within one chain vanish, and the physical properties become independent of the concentration of the solution. Only under these circumstances can it be determined whether the chain indeed forms a rigid structure at low temperatures, as the optical effects suggest that it should, and whether the state of the molecule at any given temperature can be seen in terms of a mixture only of stacked and unstacked bases, with no other, or intermediate, geometries.

All criteria for ideality are fulfilled: the conformation, as observed primarily in terms of the radius of gyration from light scattering, but also by viscosity and sedimentation, showed high rigidity at low temperature, as demanded by short-range interactions between the bases. As the temperature is raised, the stacking is progressively disrupted, and the rigid structure collapses at an early stage of this process, again in a predictable manner. The course of the transition is altogether consistent with a stacked form resembling one strand of a double-helix, though no actual geometry can of course be deduced. It is worth noting that these results are inimical to the concept, which has recently been aired, whereby thermal breakdown of stacking entails oscillations of increasing amplitude of adjacent bases relative to each other

Instead they strongly support a simple two-state stacked–unstacked equilibrium.

As to optical methods, and the assessment of stacking from such measurements, Cantor and Tinoco (*Biopolymers*, **5**, 821, 1967) have compared calculated and observed optical rotatory dispersion curves for nine trimers, seven of them trinucleoside diphosphates (no terminal phosphate). It is confirmed that there is good agreement on the basis of sums of pairwise interactions along the chain, and this work supports the validity of analyses of single-stranded polynucleotides in these simple terms. At the same time, Inoue *et al.* (*J. Amer. Chem. Soc.*, **89**, 5701, 1967) have looked at seven trinucleotides—all with the terminal phosphate group—and obtain less satisfactory agreement with calculated curves; it can be deduced that there is a considerable effect from the terminal charge. It is also found that stacking persists in several cases at alkaline *p*H, so long as not more than one of the bases in the trimer becomes ionized.

Making Safe Vaccines

from a Correspondent

At the fourth meeting of the Cell Culture Committee of the Permanent Section of Microbiological Standardization, held at the National Institute for Medical Research (Hampstead Laboratories) in September last year, much attention was given to the measures that can be taken to eliminate hazards encountered in virus vaccine production, in particular the elimination of oncogenic factors in the final vaccine. It was emphasized that more standardization both of media and of cell substrates would do much to achieve this goal.

As far as cell substrates are concerned, the tissue used on the widest scale is grown from monkey kidney. The primary tissue is not tested for the presence of extraneous agents although attempts are made to isolate viruses from control cultures throughout the period of vaccine production. The recent episode in which a number of laboratory personnel were infected by contact with the blood or tissue of a group of African green monkeys tragically underlines the dangers of using primary cultures of uncharacterized tissues. The further possibility cannot be overlooked that an undetected infectious agent may survive in the final vaccine product and become apparent only after injection into man.

Other primary tissues used for vaccine production are derived from chick and duck embryos and canine kidney. These animals are obviously bred in a much cleaner environment than obtains for monkeys in the wild, but the possible presence of extraneous agents nevertheless enjoins caution. Thus although chickens have been bred under controlled conditions which are free from fowl leukosis viruses, a new infectious agent—that of Marek's disease—has recently been isolated and only a few of the commercial flocks are free from both agents. Rabbit kidney and guinea-pig kidney are also now being used on a small scale; the absence of reported isolations of extraneous agents from primary cultures of these tissues may be due to lack of experience with these cultures rather than freedom from infection.

Any new cell substrate for virus vaccine production must be derived from normal tissue and must remain normal throughout its propagation. The cells must be frozen until they have been cleared for use by the necessary exhaustive tests. It is also necessary that such tissues should be suitable for the growth of human viruses in high titre.

Objections have been raised to the use of human tissue on the grounds that an undetected agent (oncogenic virus or "slow" virus) will be more dangerous in a vaccine to be used in man than similar viruses that may occur in animal tissue. It must, however, be pointed out that none of the primate oncogenic viruses (SV_{40} and adenoviruses) gives rise to tumours in the species in which it is indigenous, although such viruses do produce tumours in other animal species (hamsters and the like). Furthermore, "slow" viruses are known to cross species barriers (scrapie in sheep and mice), and animal tissue would therefore not be safer than human tissue in this respect.

The committee was particularly anxious that greater attention should be paid to the use of standardized cell culture media. The use of a powdered medium made in a large batch and tested for suitability before release has done much to minimize changes that can arise as a result of nutritionally deficient or drastically altered medium. Most antibiotics, although preventing the growth of bacteria, have no effect on the growth of some strains of mycoplasma and their use provides no assurance against mycoplasma contamination. Some batches of serum presumed sterile have been found to be contaminated; they may vary widely in growth promoting activity, and changing batches may occasionally cause chromosomal changes in a cell with an unstable chromosomal complement.

For obvious reasons, much attention is being given to the potential oncogenicity in man of new cell substrates. It has been suggested, for example, that a latent viral genome in the tissue may hybridize with the virus used for vaccine production and thereby be activated. In general, animal inoculation tests are insensitive for the detection of oncogenic viruses, and *in vitro* tests are urgently needed. The fusion of candidate cells for virus production with a variety of other cell types may provide a useful tool for the demonstration, or exclusion, of the presence of incomplete virus in such tissues.

The hazards of making virus vaccines stem primarily from the use of ill defined and potentially contaminated substrates. It is encouraging to learn of the increasing activity in the use of a well characterized human cell (*WI*-38) in the preparation of vaccines for clinical trial and to learn also of their use, without incident, in a total of well over a million human subjects.

Muscle Meeting

from a Correspondent

Passers-by in Gower Street just before Christmas, seeing the large notices proclaiming the "Muscle Meeting", might have been forgiven for supposing that this was a congress of weightlifters. It was in fact merely the winter meeting of the British Biophysical Society: this bore the title "Muscular Contraction" and was organized by Dr H. E. Huxley and Professor D. R. Wilkie. There was an unusually full and international programme and the meeting occupied three full days the first structural, the second biochemical and the third mechanical

The first day was cumulatively a trifle dispiriting The 380 Å and 400 Å repeats flashed across the screen for several hours until the mind reeled, and one was left with an overall impression of many speculations chasing few periodicities A member of the audience was heard to remark that it was like trying to discover how a watch worked by listening to the ticking from the outside Nevertheless there were some interesting papers the meeting began with a comprehensive and highly informative survey of the present state of structural knowledge by H E Huxley F A Pepe (University of Pennsylvania) described new work using antibody-staining to clarify the geometry of the M-line region Observations on staining with fluorescent anti-HMM antibodies in the presence and absence of ATP suggested that on contraction a distortion occurs in the trypsin-sensitive region uniting the light and heavy meromyosin entities This is an important result, the notion of such a distortion as a basis for the movement of the cross-bridges in contraction had also been hazarded by Huxley, and is evidently a concept now generally in the air

Interest was also aroused by a provocative paper by G. F Elliott and E Rome (King's College, London), who have observed the separation of the filaments of glycerinated fibres as a function of *p*H and ionic environment The observed variation has been at least qualitatively explained in terms primarily of coulombic interactions between the filaments, treated as charged rods, and the suggestion was made that the process of contraction should be viewed in terms of disturbance of these charge relationships

The second day provided the most consistently interesting part of the meeting, with an admirable paper by S Ebashi and Y Nomura (University of Tokyo) as its centrepiece These workers have made remarkable advances in analysing the relaxing system, and have isolated and characterized the protein troponin, which is found in association with the rod-like tropomyosin, and promotes its aggregation Calcium ions are involved and two categories of calcium-binding sites have been demonstrated Fixation of purified troponin antibodies gives strong evidence of its location in the *i*-filament region About one troponin molecule is present for every turn of the actin helix Ebashi also discussed α-actinin this has three components, a 6*S* protein, an aggregate of the same protein, and a complex with another protein The 6*S* protein has been shown by antibody methods to reside in the Z-band It has a large promoting effect on superprecipitation of actomyosin and gel-formation of F-actin Other components were also considered, and their location, proportions and activity were surveyed

There were interesting contributions also from A and P Dreizen (State University of New York) on the minor protein components of myosin and on active thiol groups in the myosin heads, from A G Szent-Gyorgyi (Brandeis University) on the relation of nucleotide-binding to the actin-myosin interaction, from J Gergely (Retina Foundation, Boston) on stabilization of actin conformation by divalent cations and nucleotides, and from S V Perry and his associates (University of Birmingham), particularly on the molecular weight and structure of actin, which essentially resolves a current controversy in favour of a low value (about 45,000) for the monomer molecular weight

The final day—on energetics and mechanics—yielded, among other things, some interesting observations by A F Huxley (University College, London) on the transient response of muscle to quick stretch or release, which will have to be considered in the formulation of any general theory of the contractile mechanisms, an informative review by R E Davies (University of Pennsylvania) of ATP conversion and a description of some techniques for its study, and a consideration by D R Wilkie (University College, London) of interpretation of heat and energy measurements on living muscle

The meeting as a whole drew a large audience, and the discussions were more than usually lively and informed One was left at the same time with an impression of specialized interests, and a fairly general failure to make a bridge between the three rather disparate parts of the meeting A number of new ideas were, however, aired and the return in stimulus and hard information was well above average

Earthquake in Turkey

THE UNESCO reconnaissance mission to the earthquake zone of Northern Turkey has concluded the first part of its investigations Dr N N Ambraseys of Imperial College, Dr A Zatopek of Charles University, Praha, and Drs M Tasdemiroglu and A Aytun of Imar ve Iskan Bakanlıgı, Ankara, describe their findings

The earthquake of July 22, 1967, in Turkey was felt over an area of at least 400,000 square kilometres It originated on the extension of the Bolu–Abant fault in the Mudurnu River Valley, an active part of the North Anatolian fault zone

Fig 1 shows the general trend of the North Anatolian fault zone and the extent of faulting since 1939 It is of interest to note from the figure the remarkable trend of the successive faulting along a length of more than 1,000 kilometres, consistently right lateral with the downthrown side to the north Table 1 gives a list of the most important earthquakes in the fault zone With the exception of the earthquakes of 1909 which were not documented, and of the shock of October 1944 which had its epicentre at sea, every other earthquake of magnitude equal to or greater than 6·75 has been associated with surface faulting progressing from east to west It can be shown (Ambraseys and Zatopek, *Bull Seismol Soc Amer*, **58**, 47, 1968) that the seismic energy, in ergs, released by these shocks can be expressed in terms of the length of faulting L, in centimetres, by

$$E(\text{ergs}) = 2\times10^{20} L^{1{\cdot}26} \qquad (1)$$

This suggests that the linear dimensions of the focal volume do not increase in the same proportion with increasing energy content, but that the volume of strained upper crust tends to elongate in the direction of faulting with increasing length of the rupture This is more plausible than a suggestion due to Tocher (Tocher, *Bull Seismol Soc Amer*, **48**, 147, 1958) that the volume of strained rock is not thicker for the largest shocks than for the smallest shocks that produce a fault trace

Number of events shown in Fig. 1. L, Length of faulting (km); M, magnitude; D, relative horizontal displacement (cm); T, throw (cm); h, focal depth; RH, right lateral movement.

The detailed mapping of the fault zone and the study of the damage associated with the earthquake of July 22, 1967, is now being carried out by the UNESCO Mission to Adapazari. Preliminary results show that at least 80 kilometres of new faulting occurred between Güney and Sapanca. Magnitude of displacements was variable, from a few inches to 7 ft., but the sense of lateral movement was always right-handed, and apart from local irregularities, down to the north. About 25 kilometres of surface rupture, between Güney and Dokurcum, lie within the zone of ruptures associated with the earthquake of May 26, 1957; however, the trace follows neither faults with conspicuous geological evidence of recent activity nor fault-breaks associated with the 1957 earthquake. The next 30 kilometres of faulting lie within a zone of recent tectonic movements; they do not follow faults regarded by geologists as active but produce a new trace. The rest of the fault-break is discontinuous and it is not connected with geological features that show very recent activity.

The ground movements in the fault zone were very severe and lasted about 15 sec. The first movement of the ground was horizontal and strong enough to throw down people and burden animals. This movement was followed by one or two very intense vertical shocks, in places sufficiently strong to lift boulders out of the ground without disturbing the rims of their former seats.

In spite of the intensity of the ground movements in the fault zone, there was very little damage to buildings. This is a consequence of the wood frame construction and comparatively light roofs of the local houses and also of the short duration of severe shaking. Adobe and brick structures suffered varying degrees of damage, particularly heavy at some distance from the fault zone. The mission found that it was nearly always wrong to expect the heaviest damage in the close vicinity of the fault-break. The earthquake killed 87 and wounded 235 people, destroying or damaging beyond repair about 4,000 houses, mainly of timber frame construction. Improperly designed or constructed reinforced concrete structures suffered heavy damage as far as Izmit, 70 kilometres from the fault zone.

The mission found it practically impossible to assess intensities in the epicentral area. On purely vibrational criteria the maximum intensity did not exceed IX on the Modified Mercalli scale. On the basis of the scale, however, the fact that "objects were thrown into the air and lines of sight and level were distorted" implies an intensity XII (MM). This shows how imperfect existing Intensity scales are.

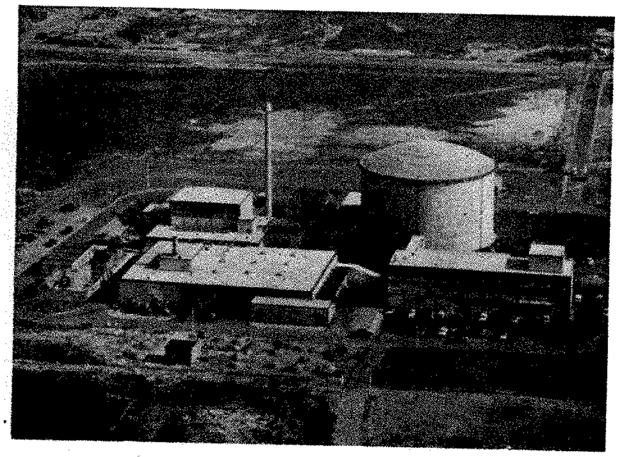
European Nuclear Energy

by
NIGEL HAWKES

Collaboration in Europe is not the rallying-cry it used to be. Organizations set up in the heyday of collaboration are having to adapt to new conditions.

THE European Nuclear Energy Agency is now ten years old, and, like other organizations set up in the fifties, is finding that times have changed. The revival of economic nationalism led by France has meant that organizations which make a virtue of unanimity have found the going hard. Euratom, for example, has been crippled by the reluctance of its members to approve a budget for 1968. The difficulties of ELDO are by no means over. The more flexible organizations have on the whole been more successful in adapting themselves to the new climate, a conclusion which is perhaps no more than a glimpse of the obvious. In these circumstances, the suggestion has been made that Euratom should modify its structure to enable individual countries to opt out of individual contracts without endangering the whole organization. ENEA may well be quietly congratulating itself—its constitution provides exactly this kind of flexibility. This is one of the reasons why ENEA is confident of its future, despite the real doubts about the form it will take.

The most important doubt is about Britain's ability to get into the Common Market. Because this would also mean getting into Euratom—there is no real distinction between the two since the three Common Market commissions were merged into one—it would have a marked effect on the relations between Britain and the ENEA. But until then, there seem unlikely to be any dramatic shifts of policy for the ENEA. There will, however, be a continuing tendency for projects begun by ENEA to be shifted to a world basis under the wing of the International Atomic Energy Agency. In particular, the work on information retrieval and dissemination is already going this way. A plan for a European Distribution Centre for nuclear reports has been shelved for the time being because the IAEA has announced its own plans for a world-wide International Nuclear Information System. In the absence of the European Centre, the ENEA plan is being put into operation through the services of the British National Lending Library for Science and Technology at Boston Spa—if the centre is ever built, it would be intended ultimately to form part of the international system.



The Dragon reactor at Winfrith in Dorset. (UKAEA photograph.)

ENEA EXPENDITURE, 1966–67

	$ million
Headquarters (Paris)	0·5
Ispra and Saclay	0·4
Dragon	6·5
Total so far	71·5
Halden (for the period 1963–69)	9·2
Eurochemic (to meet budget deficits)	5·3

ENEA has been responsible for supporting three important projects; the Dragon high temperature reactor at Winfrith in the United Kingdom, the Halden reactor in Norway, and the Eurochemic fuel re-processing plant at Mol in Belgium. All three are long-standing contracts—Halden came into being in 1958, and Dragon dates from a year later. Both the Halden and Dragon agreements have been extended; Halden comes to an end in 1969, and Dragon is to finish in 1970. In the case of Dragon, however, much will depend on whether Euratom can agree on the budget—at the moment the project is being kept in being by the United Kingdom and the other countries in ENEA who are not members of Euratom. By common agreement, the Dragon project has been a very happy example of collaboration, and has demonstrated the feasibility of the high temperature reactor principle. It has also led to some very optimistic assessments of the economics of fast reactors—in the annual report of the ENEA, just published (OECD, Paris), fuel cycle costs of 0·12–0·13 d per KWh and generating costs of about 0·465 d per KWh are predicted for a 528 MW(e) station. These figures (converted at the new parity of the pound) make high temperature reactors seem an attractive possibility.

The Halden project now finds its principal use as an irradiation facility for testing fuel assemblies. The reactor is of the boiling heavy water type, built originally by the Norwegian Institutt for Atomenergi. Eurochemic, the fuel re-processing plant set up at Mol, came into operation in July 1966. In principle, it is expected to be self-financing, but in the current state of the nuclear fuel business it is unable to make profits. The main difficulty is that there is considerable over-capacity in fuel re-processing, which means that nobody is making much money. As nuclear power expands in Europe, the position could improve, but there seems to be a danger that Eurochemic will be left only the work which member countries are unable to do themselves. The annual report, for example, gives information about a contract lasting ten years to re-process the fuels from the VAK reactor at Kahl and the KRB reactor at Gundremmingen in West Germany. But the contract only covers the amounts of fuel which cannot be handled by a German re-processing plant being built at Karlsruhe. Eurochemic will have to console itself with the thought that if member countries do not use its facilities fully, they will find themselves paying for its deficits. Already the OECD council has agreed that up to $5.3 million should be made available for 1968 and 1969 to cover expenses not covered by receipts.

ENEA also supports a variety of smaller projects. The computer programme library at Ispra in Italy, originally set up for a three year period, is now to continue indefinitely. The library receives computer programmes from member countries, checks them, and then sends them out to interested organizations. Because the checking process normally costs about $1,000 for each programme—and every programme needs correction—the library is a way of avoiding costly duplication in the member countries. Another centre, the Neutron Data Compilation Centre at Saclay, contains a library of neutron data, and the Seibersdorf Project, near Vienna, is a way of gaining experience of the possibilities of food preservation by irradiation. The agency has also been involved in the problems of the disposal of radioactive waste. The latest annual report of the agency gives details of the first dumping of radioactive waste it has organized. Five countries—Britain, France, West Germany, Belgium and the Netherlands—agreed to take part in the experimental programme, and 11,000 tons of packaged waste was collected together, securely packaged and dumped at a depth of 16,400 ft in the eastern Atlantic.

In addition to this, the agency organizes a number of joint committees, covering such subjects as reactor safety, reactor physics, magneto-hydrodynamic power generation and nuclear data. Increasingly, it seems that the agency is moving away from large projects, principally because these are no longer wanted by member countries. Since nuclear power became a commercial activity, collaboration has seemed less and less attractive. But there is now a suggestion in the air for a large scale project in the fast reactor field, and a meeting of ENEA's top scientific committee, with representatives from all member countries, will be discussing the proposal next month. If enough of the countries are interested, the proposal could become a reality, but in the present climate this is unlikely. The United Kingdom, which has already been responsible for shelving one ENEA proposal, for a ultra-high flux research reactor, is unlikely to feel that this is the time for undertaking new expenditure abroad, particularly in a field in which the UKAEA has already made substantial investment at home. The UK would have little to gain and a great deal to give away in a project of this sort. And Euratom is too busy deciding (more accurately, failing to decide) its own research programme to take any interest. It rather looks as if ENEA will have to content itself with more modest projects for the next few years.

Is the Special Theory Right or Wrong?

In *Nature* for October 14, 1967, Professor H. Dingle argued that the special theory of relativity is incorrect, and Professor W. H. McCrea put an opposing view. Some correspondence on the same subject has already appeared. What follows is a further selection from the correspondence on this subject.

Experimental Verifications of the Theory of Relativity

As a postscript to the articles by Professor H. Dingle[1] and by Professor W. H. McCrea[2], we should like to draw attention to two recent experiments which bear directly on items which Dingle has felt obliged to doubt, but which have been mentioned in "News and Views"[3]—the relativity of time as exemplified, in particular, by the "clock paradox" (ref. 4) and the second postulate of the theory of relativity, which asserts that the velocity of light is independent of the motion of the source[5]. The apparent slowing down of moving clocks, long ago verified for straight-line motion[6], has now been established for a circular trajectory as well, a time-dilation factor of 12 being verified to within 2 per cent. In another experiment, bursts of γ-rays emitted from fast moving π^0 mesons have been timed as they cross the laboratory, the velocity obtained is equal to the standard value for the velocity of light c to within 1.3 parts in 10^4 even though the source velocity is itself very close to c.

The result on time-dilation is obtained as a by-product of another investigation. In the muon storage ring[7] at CERN, muons of momentum 1.274 GeV/c are injected into a circular orbit in an almost uniform magnetic field. The design includes vertical and horizontal magnetic focusing to prevent loss of particles. The circulating muons can be detected by means of the decay, $\mu^- \rightarrow e^- + \nu_\mu + \nu_e$ for the electron produced, which has less momentum than the parent μ^-, is bent more sharply in the magnetic field and emerges towards the centre of the ring. Some of these electrons are detected by counters, the number observed at any time being proportional to the number of muons left in the ring at this time. The lifetime of muons at rest is $\tau_0 = (2.200 \pm 0.0015)$ μsec (ref. 8), and special relativity then predicts for the muon in flight, the dilated lifetime $\tau = \tau_0 \ (1 - v^2/c^2)^{-1/2} = 26.72$ μsec. Here it is assumed that no special correction is necessary when the orbit is deflected by a magnetic field, and that the decay rate of the particle in its rest system is not altered by the acceleration experienced. The observations[7] (see Fig. 1) show an exponential decay with lifetime 26.15 ± 0.03 μsec, agreeing with the theory to about 2 per cent. (The marginally shorter lifetime is ascribed at present to a slow loss of muons, perhaps as a result of imperfections in the magnetic field.) This result removes any lingering suspicion that some unsus-

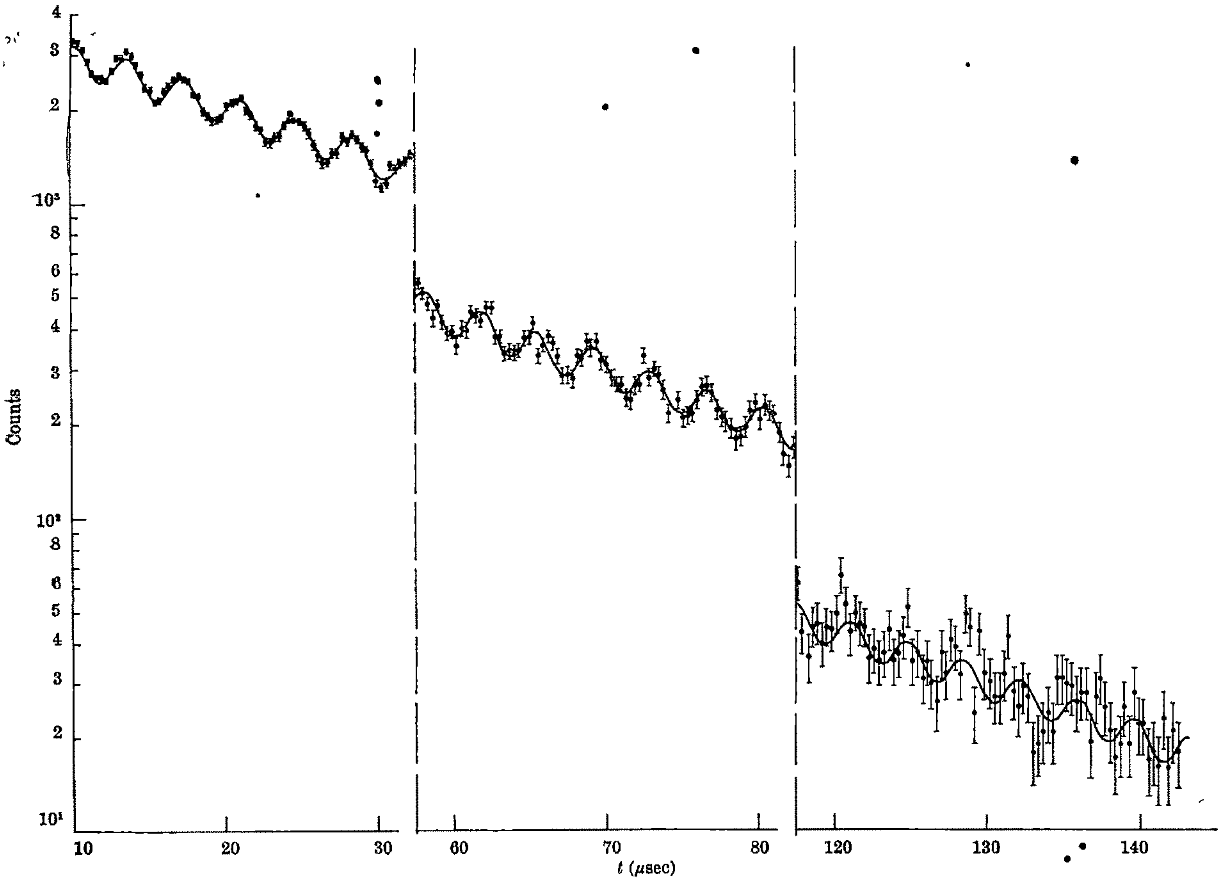


Fig. 1. Decay electron counting rate from stored muons (log-scale) plotted against time. Fitted lifetime $\tau = 26.15 \pm 0.03$ μsec. The small oscillations are due to the precession of the muon spin (see ref. 4).

pected effect associated with acceleration would compensate the time-dilation in a circular or out-and-return journey, the "clock-paradox" is established as an experimental fact associated with the time-keeping of radioactive material in direct comparison with standard laboratory scales of time.

The possible influence of source velocity on the velocity of propagation of γ-rays has also been studied at CERN. When 19 GeV protons hit a beryllium target in the proton synchrotron, the resulting forward-emitted γ-rays have a sharp pulse structure in time as a result of the bunching of the protons in the accelerator by the applied radio frequency. By measuring the time of arrival of the γ-ray bunches ($E_{\gamma} > 6$ GeV) at two points along the beam, and comparing in each case with the radio-frequency phase, the velocity is obtained as a simple product of a laboratory distance (31.4503 metres) and the radio frequency applied to the synchrotron (9.53220 MHz). Including small corrections, the result is $(2.9979 \pm 0.0004) \times 10^{10}$ cm/sec^{-1} (ref. 9), agreeing with the standard velocity of light c to 1.3 parts in 10^4.

In such a high-energy collision, the velocity of the centre of mass is a substantial fraction of c, so it can hardly be doubted that the γ-rays come from a moving source. That the γ-ray spectrum observed in such collisions is dominated by the production of π^0 mesons[10] (followed by $\pi^0 \rightarrow 2\gamma$ giving in the π^0 rest frame two γ-rays of 70 MeV) was established first for cosmic ray events[11] and later in the laboratory[12]. Both the γ-ray intensity and the spectral shape are explained by this hypothesis, admittedly with the use of the relativistic formula for the Doppler shift. In the present experiment, γ-rays with $E_{\gamma} > 6$ GeV are selected, and the corresponding π^0 must have (according to relativity) $V_{\pi^0} > 0.99975\ c$. It is concluded that the second postulate is verified accurately even for very high source velocities.

The Michelson–Morley experiment has shown that the velocity of light is not changed by the motion of source and detector together. Combining with the above result, one may conclude that neither the motion of the source nor the motion of the detector influences the velocity.

The earlier double star observations and other experiments are discussed in ref. 6, including difficulties in interpretation raised by the extinction theorem.

The Error in the Special Theory of Relativity

IN his recent article, McCrea[1] explains the apparent contradiction in the results obtained by Dingle[2] from the special theory of relativity by pointing out that Einstein used two symbols to represent four different quantities. They are defined by Einstein quite carefully and distinguished by qualifying phrases which do not, however, appear in the mathematical treatment. When I discussed this ambiguity some years ago[3,4], I suggested that if Einstein had used four separate symbols he would have avoided the mistake which he made later in his paper. This occurs in the round-trip "thought experiment" in which one of the essential qualifying phrases is omitted even in his descriptive account, thus leading to an incorrect result[5,6]. A brief reference is made to this "experiment" in a comment in *Nature*[7] in which it is stated that the symmetry of the clocks is not preserved. Now this would be true in practice, but Einstein made no mention of any effects caused by acceleration nor did he make any allowance for them. If the "experiment" is carried out correctly it should therefore give the same readings for the clocks as they would have when they are in uniform relative motion. The result given by Einstein does not follow from the "experiment" but from an assumption made implicitly that the clock which does the round trip is actually going slower than the one regarded as stationary and does not simply appear to go slower as viewed by the stationary observer.

This assumption may well be correct and is certainly reasonable. The important point to appreciate is that an additional assumption has been made. The confusion has arisen because of the belief held by Einstein and most writers on the subject that the result of the round-trip "experiment" follows from the initial postulates.

Einstein stressed the tentative nature of his theory and the need for experimental checks. Contrary to popular belief, there is no evidence concerning the special theory as propounded, because no experiment has been made in a force-free space. In practice, gravitational forces or accelerations are always involved[8]. There is now a certain amount of evidence that frequency shifts occur when atomic clocks are at different gravitational potentials or are subjected to rotational acceleration[9,10].

The Case against the Special Theory of Relativity

PROFESSOR MCCREA's reply[1] to my disproof of special relativity[2] is both gratifying and disappointing. It is good that, at long last, some comment has appeared, regrettable that this one contains nothing to the point.

One simple thing only is needed to refute the disproof, and it is essential—to show an error in the derivation of my equation (4) that does not invalidate equation (3). This I showed with unmistakable clearness. McCrea's only contribution to it is the following: "Dingle's (3) is meaningless. Correspondingly his (4) is meaningless." This, if true (it is not), would merely kill the theory in another way, for (3) is Einstein's deduction and that of all his followers until now.

Because this conclusively nullifies McCrea's rejoinder, I should leave the matter here, with a final appeal to him now to agree frankly that the theory is untenable, but for the fact that the overlooking of the irrelevant bulk of his statement would, in the prevailing state of thought, be misinterpreted. *Nature's* prediction[3] that "The chances are that most people will be persuaded by what [McCrea] has to say" would only too probably be verified. It is the general view that relativity is beyond the understanding of most, but must be accepted because some mathematicians, who alone understand it, have endorsed it: criticism of it, being on this view merely a sign of incomprehension, can therefore be ignored if a sufficiently imposing mathematical dismissal, intelligible or not, is forthcoming. Euler faced the non-mathematical sceptic, Diderot, with the challenge "Sir, $a+b^n/n=x$, hence God exists, reply!" Diderot did not reply and Euler's case prevailed. McCrea's statement has the same relevance and cogency as Euler's, and if met with silence would produce the same general conviction. Reluctantly, therefore, I dissect it.

First, all the didactic, as distinct from the polemical, part which expounds the mathematics of the theory is superfluous; I do not question it. I distinguished clearly between (*a*) the mathematics and (*b*) the identification of the mathematical symbols with observable quantities. I have enough mathematical insight to see that it is a waste of time to look for mathematical flaws in the theory. Hence McCrea's argument (i), which he says "alone is sufficient to refute Dingle's contention", does not touch that contention. Of course, "equations (III) and (IV) [my (1) and (2)] concern two distinct sets of events, and so they cannot contradict each other". But what McCrea has to show, and has not shown, is why the physical result (3), deduced from one set, can be held true, while the physical result (4), similarly deduced from the other (non-contradictory) set, must be held false.

Not only do I agree that my equations (1) and (2) are mathematically free from contradiction, I agree also that it is perfectly possible (though, of course, not necessary) that if the experiment were made the clocks described would give readings conforming to (1) and (2) (in which case, as far as can be seen at present, we should have to accept Lorentz's theory). But what is impossible is that, in that case, the settings of *H* and *N* in relation to *A* and *B*, respectively, which, according to Einstein's definition, synchronize the pairs, *A*,*H* and *B*,*N*, would be such as to enable us to infer both his reading of *A* for an event occurring on *H* (thus yielding (3)) and a similarly determined reading of *B* for an event occurring on *N* (thus yielding (4)). This I clearly stated.

McCrea's comments on this essential point of synchronization, which alone enables us to compare the readings of separated clocks, are revealing. If Einstein's comparison were, as he says, merely one of "two different ways of putting the readings of A,B into 1–1 correspondence with each other", the whole theory would be an idle mathematical fancy, and a space traveller would return either older or younger than his twin brother according to our capricious choice of correspondence This, which I also clearly pointed out, McCrea ignores We have here another equivoque of the kind which I exemplified by the oscillating interpretation of the "FitzGerald contraction" Either special relativity says nothing physical, or its (physical) statements are contradictory To establish his choice regarding asymmetrical ageing, McCrea supposes that it does speak[4], and selects arbitrarily only one of its contradictory utterances When asked to face the other he shifts his ground and denies that the theory has said anything at all The recognition and abjuration of this specious ambivalence are long overdue

But the passage which shows the deepest misconception is this "About the first thing that relativity theory does is to deny any operational meaning to the notion of simultaneity at two different places Naturally, this fundamental feature in the theory is not affected in the slightest by any arbitrary conventions we may adopt for the synchronization of clocks" What Einstein pointed out (and this shows his great insight into the matter) was that there was no natural meaning of such simultaneity, one could freely be given "by definition" This released him from the previously assumed necessity to assign distant times in conformity with Galilean kinematics and set him free to base a theory on whatever operational definition he chose—the theory then, of course, being riveted to that definition and subject to test by observation But when the observation which it requires is seen to be that one clock goes both faster and slower than another, you cannot plead that that is only because of the arbitrary definition, which does not affect the theory in the slightest The theory is based on the definition, and if you want to regain your freedom to choose another, you must first repudiate the theory and then start again from scratch McCrea's assertion is equivalent to saying that one's freedom to marry any woman who will consent is not affected in the slightest by the fact that one has already married

Here is Einstein's own account of the matter[5] "In order to give physical significance to the concept of time, processes of some kind are required which enable relations to be established between different places It is immaterial what kind of processes one chooses for such a definition of time It is advantageous, however, for the theory to choose only those processes concerning which we know something certain" How it could be advantageous for the theory to be so particular about a process that does not affect it in the slighest is incomprehensible

McCrea's remaining arguments are based on an indefensible misreading of my phrase, "A must be held to read t_1 at E_1" He takes this to imply that I imagined A to be at the place of the event E_1, which no sane person could do "A is not 'at' E_1 in any sense admitted by the theory and it simply has no meaning whatever within the theory to speak of what A must be held to do at E_1", he writes, and he proceeds to draw a space-time diagram that "makes it perfectly clear that α [the world-line of A] does not go through E_1, and so there cannot possibly be a reading of A 'at' E_1" I myself had defined A as a clock permanently distant from H (on which E_1 occurs) and had so shown it in each of four drawings I cannot believe that anyone, reading the phrase in its context, could fail to see that "A must be held to read t_1 at E_1" meant that the reading of A, which, according to the theory, must be associated with the event E_1, is t_1 My definition of E_1 as the coincidence of H and B was accompanied by one of the drawings showing A unmistakably at a distance from that event, and, similarly, another drawing showed B at a distance from E_2 That McCrea should have found it necessary to draw a complex of world-lines which obscures for the non-specialist what my simple figures had already made clear to all can be explained only in Eulerian terms That is not the way to get at the truth, and I am not Diderot

The letters of Dr Barrett[6] and Mr Fullerton[7] reveal elementary misconceptions, and Barrett writes "for A, these two clocks are not synchronized" Synchronized clocks are not synchronized for A or for B, they are simply synchronized The process is experimental if the readings satisfy the condition, $t_3 = t_2 - t_1$, given in my article, the clocks are synchronized absolutely Barrett confuses clock-readings with the times at which the clocks have those readings the same reading is collected, fast or slow, according to the co-ordinates system chosen, but the reading is absolute Clock-readings alone are involved in my disproof of special relativity That is why Einstein rightly concluded that his theory required one clock to work absolutely more slowly than the other Fullerton refers to an observer who "synchronizes A, B, H to zero but not N" Clocks are not synchronized to one reading, synchronized clocks give a common reading in every event B cannot be synchronized with A and H, for it moves with respect to them If Fullerton means only that these clocks read zero at the event E_0, then so does N, but the fact is trivial

I now sum up the situation by stating again what must be done to avoid my conclusion Either my equations (3) and (4) are contradictory or they are not If they are, at least one must be wrong, and if Einstein's (3) is right, then a false step must exist in the deduction of (4) from the commonly agreed (1) and (2) which has no repercussions on the deduction of (3) this false step must be pinpointed If, on the other hand, (3) and (4) are not contradictory, then it must be explained why Einstein's deductions from (3)—for example, that an equatorial clock goes slower than a polar one—are true, while the similar but opposite deductions from (4)—for example, that an equatorial clock goes faster than a polar one—are not equally true In each case, therefore, either the necessary physical implications of (3) must be vindicated and those of (4) discredited, or the theory fails No solution which makes the equations equivalent, whether meaningful or meaningless, has any bearing on the matter

Special Theory of Relativity

I HAD supposed that the misunderstanding about the "preferred clock", mentioned by Professor Dingle on page 121 of your issue of October 14, arose from attempts to apply the equations of special relativity in a frame which was not "inertial" This seems consistent with what is said in your editorial comment on page 113 about the application of external forces, but it does not seem to explain the statement attributed to Einstein on page 121 if that statement is to be considered in the context of the special theory

The velocity of a point on the equator relative to the pole can presumably be taken as zero in the frame of an observer on Earth What preference is to be given or denied to that frame ?

The Jodrell Bank Mark III Radio Telescope

by
H. P. PALMER
B. ROWSON
Nuffield Radio Astronomy Laboratories,
University of Manchester,
Jodrell Bank

A radio telescope which can be dismantled and reassembled at a new site within 6 months is now being used for interferometer measurements in conjunction with fixed instruments at Jodrell Bank.

SURVEYS have been published[1-4] of the angular sizes of approximately 400 discrete radio sources. Many of these measurements have been made at Jodrell Bank by using the Mark I (ref. 5) or Mark II (ref. 6) telescope linked with smaller telescopes at distant sites to form instruments which are the radio analogues of Michelson's stellar interferometer. The early surveys made it clear that this programme should be extended to fainter sources. This could be achieved with a larger telescope at a remote site. It was also clear that if that telescope were fully steerable, a tracking interferometer[7] would be available to obtain information down to a few seconds of arc about the angular structures of more than a thousand radio sources.

In 1963, a formal request was made to the Department of Scientific and Industrial Research for a grant towards the design and construction of a Mark III radio telescope, of the same size as the Mark II (125 feet by 83 feet 4 inches) and fully steerable. The telescope is intended primarily to be used with the Mark I instrument for interferometric observations at wavelengths down to 21 cm. Because it is not known which separation will be most significant for these measurements of weak sources, the telescope was also designed to be transportable. This implies that the time taken to dismantle it and re-erect it elsewhere should be only about 6 months.

The Mark III telescope was designed by Husband and Co., consulting engineers, of Sheffield and London, to be suitable for automatic operation by remote control by means of radio links and to have a good radio performance at wavelengths of 21 cm and longer. The telescope has been constructed by Fairey Engineering as main contractors with a number of sub-contractors. After some delays in completion and commissioning, it finally came into full service as an interferometer in July 1967 and has been working almost continuously since that time. Fig. 1 is a photograph of the instrument seen from the south-west at its first site, near Nantwich. The focal laboratory is supported on a quadrupod of steel girders. It consists of a temperature controlled enclosure approximately 8 foot cube which is generally similar to that on the Mark II telescope. Access is by a stairway up one of the girders which can be reached from the ground when the bowl is directed to the horizon. The reflecting surface consists of a square mesh of galvanized wires 1 inch apart, which has the correct parabolic shape within a tolerance of 0·5 inch. The radio performance of the reflector has been tested at wavelengths of 21, 18 and 11 cm. It gives approximately 81 per cent of its theoretical performance at 21 cm when directed to the zenith, but the performance at 11 cm is 45 per cent at the zenith. As the telescope is directed to lower elevations, the structure deforms under gravity by not more than 1 inch r.m.s., and at a wavelength of 11 cm the reflector efficiency falls to 14 per cent, when the telescope is directed at the horizon. Thus, the telescope performs satisfactorily at the lower specified wavelength of 21 cm and has a useful performance, particularly at high elevations, down to 11 cm.

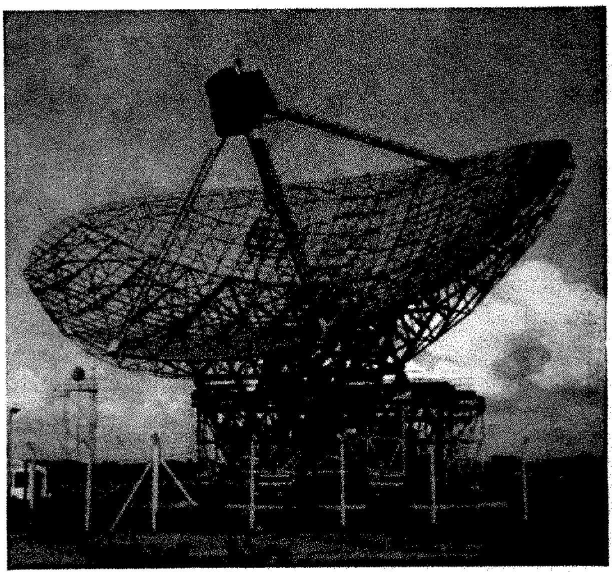

Fig. 1. The Mark III radio telescope at its first site 24 kilometres south-west of Jodrell Bank. The hut containing the receiving and control equipment, and the tower carrying the radio link aerials, can be seen to the left of the telescope.

At an early stage it was decided to use hydraulic drive systems for both motions. The drive in azimuth on the 60 foot diameter rail track is provided at two of the six bogies, while the motion in elevation is controlled by two hydraulic pistons each approximately 16 feet long. A 5 horse-power electric motor drives separate hydraulic pumps for the elevation and the azimuth systems. The telescope can be driven in each motion at speeds of 5° per minute, or at one of three pre-selected lower speeds. These motions can be controlled locally or, as is now more usual, from Jodrell Bank through the UHF and microwave radio links. (Details will be described elsewhere by B. Rowson.) The attitude of the radio telescope is indicated by magslips, and their dials can be viewed by a television system on the microwave link. In addition, this attitude is continuously communicated to Jodrell Bank by signals sent over the microwave link, which drive magslip repeater dials on the remote control console. During remote operation of the telescope, the site can be viewed by television camera and the

R 351

control dials can also be inspected at will. When the Mark III telescope is used in conjunction with the Mark I, it can be arranged that the magslip signals from the two telescopes are compared and differences can be used to actuate the hydraulic motors of the Mark III. The two telescopes then move in step to an accuracy of 2 or 3 minutes of arc, and the Mark III moves at an appropriate low speed for approximately 10 seconds in every half-minute.

The hydraulic rams and motors are protected by a comprehensive system of over-pressure alarms, cut-outs and relief valves. During operation, two alarm systems are used to detect any dangerous malfunction of the control or driving of the telescope. The first sounds warning tones at the telescope, while the second sounds tones and flashes lights at Jodrell Bank. These alarms operate if the telescope approaches the end of its permitted travel in any direction, if unexpectedly high hydraulic pressures are generated in either the elevation or the azimuth system or in the event of unexpectedly high wind speeds at the remote site. At the present stage of the programme, it is normal practice for the scientist operating the telescope from Jodrell Bank to use a television camera to observe the control panel and the telescope itself periodically. In due course, it is possible that some of these control and monitoring functions will be taken over by the Argus 400 computer at Jodrell Bank.

The first site selected for the Mark III telescope gives a baseline to the Mark I of 24 kilometres length in azimuth 225°. The effective resolving power of this baseline and the position angle in which it is obtained change as the source being observed moves across the sky. These effects are shown in Fig. 2 for sources at declinations 0°, +20°, +40° and +60°. The resolving power at any instant may be represented by a vector drawn from the origin to the point on the appropriate curve at the hour angle of observation. It will be seen that for circumpolar sources all position angles can be obtained, but that for sources south of the celestial equator the range of resolving power and position angle is comparatively small. This diagram is applicable at any wavelength, but the scales on the x and y axes will vary with the wavelength of observation. The range of source sizes which can be investigated in the various frequency bands allocated for radio astronomy is shown in Table 1. Column 1 gives the observing frequency and column 2 the separation of the telescopes in wavelengths at that frequency. In column 3 are listed the angular sizes of radio sources having gaussian distributions of surface brightness which would give fringe visibilities $\gamma = 0{\cdot}8$ and $\gamma = 0{\cdot}2$. It will be seen that at this baseline we shall be able to concentrate on sources smaller than 20 seconds of arc and at the shorter wavelengths go down to sources smaller than 1 second of arc.

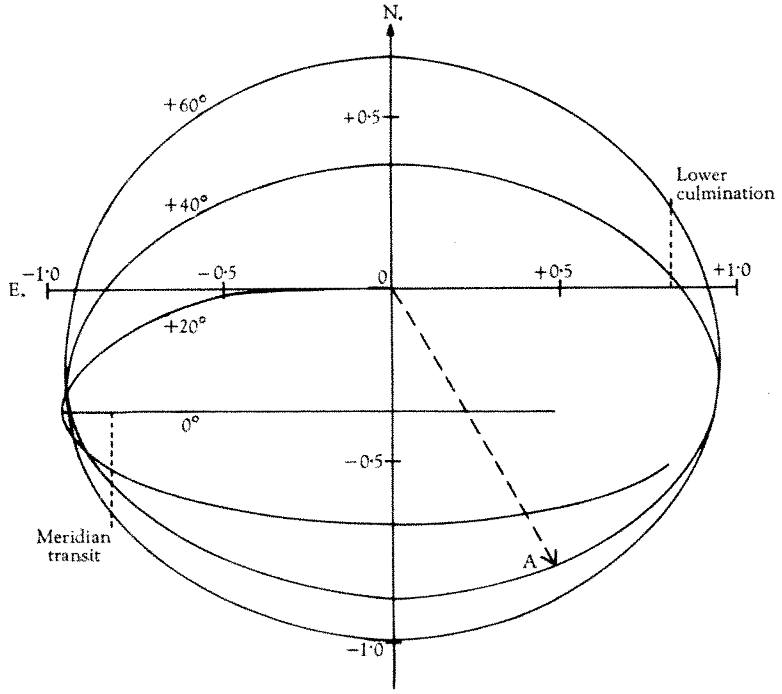

Fig. 2. These curves show the variation with hour angle of the effective resolving power and its position angle for the Mark I–Mark III baseline. Curves are shown for sources at declinations 0°, +20°, +40° and +60° for the hours when they are above the horizon. The resolving power obtainable at any instant may be represented by a vector from the origin to a point on the appropriate curve. An example, OA, is the vector for a source at hour angle 06^h, dec +40°.

Table 1. RANGE OF THE ANGULAR SIZES OF RADIO SOURCES WHICH CAN BE MEASURED WITH THE MARK I–MARK III INTERFEROMETER AT A NUMBER OF FREQUENCIES

Frequency (MHz)	Maximum baseline (No. of wavelengths λ)	Size of source (sec of arc) giving fringe visibility γ	
		$\gamma = 0{\cdot}8$	$\gamma = 0{\cdot}2$
38	3,000	17″	40″
151	12,000	4·25″	9″
408	32,000	1·5″	4″
1420	112,000	0·45″	1·5″
2695	213,000	0·23″	1″

In addition to the radio tests mentioned earlier, interferometric observations have now been completed during observations of flare stars and of a few interesting strong radio sources at 38 MHz. Brief initial programmes at 408 MHz and 151 MHz have also been carried out and some of these first results were described recently[8].

Kinetics of Association of Carbon Monoxide with Haemoglobin at Low Temperature

by

R. BANERJEE
P. DOUZOU
A. LOMBARD

Service de Biophysique,
Service de Biospectroscopie,
Institut de Biologie Physico-chimique,
13, rue Pierre Curie, Paris 5

Carbon dioxide binds to haemoglobin at −55° C, in methanol and water, in a manner basically similar to binding in ordinary conditions.

FOR a long time the combination of haemoglobin with gases has been studied chiefly by measuring dissociation curves. Such equilibrium data have led to the discovery of the haem–haem interaction, and until some years ago were the only basis of its quantitative assessment. Since the development of flow methods for the measurement of rapid kinetics and particularly that based on flash photolysis of HbCO, attempts have been made to describe the phenomenon in terms of kinetic parameters.

The kinetic and thermodynamic parameters of this reaction may not always be related in a simple manner, but some well defined kinetic expressions seem to apply to the haem–haem interaction. Particularly instructive is the comparison of the combination velocity constant obtained by rapid mixing with that observed after photolysis. The combination of haemoglobin and carbon monoxide when the two components are mixed follows a time-course mostly described by a second order rate constant (l') of about $1{\cdot}2\times10^{5}$ M^{-1} sec^{-1} at 20° (ref 1). When observed after flash photolysis, particularly after very limited photodissociation (to about 5 per cent), the combination rate is much faster[2]. Gibson originally assimilated these rapid kinetics with l'_4, the fourth combination constant in the Adair model; more recent data[3] in concentrated salt solutions (on $\alpha\beta$ sub-units) might justify a revision of nomenclature, but the basic concept relating this difference (between l'_4 and l') to the haem–haem interaction seems to be well founded.

When the light energy used for photolysis is sufficient to induce total photodissociation, the combination reaction is biphasic, an initial rapid phase (with a rate constant about twenty times as great as l') is followed by a slower phase with a rate essentially equal to that obtained by mixing (l').

The situation on and after flash photolysis of HbCO in the presence of excess carbon monoxide has been described by Gibson[4] as

$$\mathrm{HbCO}\xrightarrow{h\nu}\mathrm{Hb}^{*}+\mathrm{Hb}+\mathrm{CO}$$
$$\mathrm{Hb}^{*}+\mathrm{CO}\xrightarrow{l^{*}}\mathrm{HbCO}$$
$$\mathrm{Hb}+\mathrm{CO}\xrightarrow{l'}\mathrm{HbCO}$$
$$\mathrm{Hb}^{*}\xrightarrow{k_1}\mathrm{Hb}$$

He called the species Hb* a quick reacting form of haemoglobin which, while combining with carbon monoxide at a much faster rate (l^{*}) than does ordinary haemoglobin (l'), is itself unstable, and reverts quite rapidly to the ordinary form. The experimental reaction rates obtained by Gibson were complex, but fitted with this scheme when chosen numerical values were assigned to l^{*}, l' and k_1. He also reported activation energies for each of these reactions.

Whatever the underlying phenomena, the overall rate $\left(\frac{d\,\mathrm{HbCO}}{dt}\right)$ was dictated by a number of concurrent reactions, some of them quite fast at ordinary temperatures. We think that measurements made at widely different temperatures might in in such cases make resolution easier, for the rates of different reactions would vary by amounts determined by their respective activation energies. It is usual to operate down to 0° C, but regions below this have so far hardly been explored except in a few cases[7].

We have tried to follow some such haemoglobin kinetics at a low temperature (−55° C) in mixtures of methanol and water. The choice of the solvent at a given temperature is dictated by the stability of the protein which in this case might depend on the dielectric constant of the medium. A mixture of methanol and water 60v/40v has a reduced polarizability (compared with water) at ordinary temperatures, but the dielectric constant is close to 80 at about −55° C (ref 8). Preliminary tests showed that haemoglobin and its liganded forms (HbO_2, HbCO) are not only quite stable in these solvents but could be made to undergo the usual cycle of transformations.

$$\mathrm{Hb}+\mathrm{O_2}\rightarrow\mathrm{HbO_2},\ \mathrm{HbCO}\xrightarrow{h\nu}\mathrm{Hb}+\mathrm{CO},\ \mathrm{Hb}+\mathrm{CO}\rightarrow\mathrm{HbCO}$$

The visible absorption spectra of the respective species are not significantly different from those in water, the kinetics of these transformations can thus be followed spectrophotometrically in the usual bands.

The dark reactions were found to be much slower (by several orders of magnitude) at a low temperature than at an ambient temperature, as might be expected. The reaction, $HbO_2+CO\rightarrow HbCO+O_2$, proceeds so slowly at −55° C (even in the presence of an excess of carbon monoxide) as to be imperceptible, no doubt because of the rate-limiting step, $HbO_2\rightarrow Hb+O_2$, which, already slow (12 sec^{-1}) at 19° C and pH 9.1 (ref 9), is almost stopped at low temperature.

We report here some observations on the kinetics of the combination of carbon monoxide with haemoglobin after photodissociation of HbCO at −55° C. In one series of experiments, photodissociation was designed to be small

(5–10 per cent of total HbCO). The other series of experiments involved a much greater degree of initial photodissociation.

The optical cuvette, 10 mm long (for measurement), 3 mm thick (for photolysis) and 45 mm high, was sealed to a long cylindrical tube. It was placed in the centre of a quartz cryostat (with two pairs of parallel flat windows) where circulating cold gaseous nitrogen, measured with a thermocouple immersed in the solution itself, ensured (to ±2° C) the desired temperature[10]. The cuvette and cryostat were placed in the upper (measurement) compartment of a recording spectrophotometer, the Cary 15. A photographic shutter screwed over a hole in the external shield let in the photolysing light when desired. The latter consisted of a parallel beam recovered integrally from a mercury source of 200 W and filtered across a rectangular water trough. Except when longer exposures were wanted the shutter was set 0.25–1 sec. The recording was started manually, and so about 1 sec was lost after the end of the period of illumination. This lost time did not prove to be a serious handicap, for all the reactions were found to have slowed down and more than 50 per cent of the overall reaction could be recorded even in cases where there was a rapid phase.

The experimental solution was manipulated under nitrogen and contained at all stages an excess of dithionite. The following example describes the procedure for a typical preparation containing, say, 2.6 µmolar HbCO, 56 µmolar CO, 60 mmolar *tris* buffer, and with a solvent composition of 60 methanol/40 water, at −55° C. For solvent (+CO) 1.90 ml of deoxygenated methanol +0·95 ml of deoxygenated buffer solution (0.2 molar, *p*H 7.8) were mixed at 20° C. with a pinch of dithionite to ensure removal of traces of oxygen. Then 0.142 ml. of water saturated with carbon monoxide at 20° C was added under 1 atm pressure. The mixture (always under nitrogen) is immediately cooled to −55° C.

For HbCO which is 3.43 mmolar in aqueous buffer saturated with carbon monoxide at 20° C in the presence of a few crumbs of dithionite, 0.2 ml of the solution cooled to 0° C was added under nitrogen to 0.2 ml. of methanol at 0° C. A sample (46 µl.) of this mixture at 0° C was added immediately afterwards to the solvent at −55° C. The final solution thus has the required composition. The intermediate dilution in methanol (to 50 per cent) at 0° C is indispensable in order to avoid freezing.

In order to ensure that no denaturation had occurred, the following precautions were taken. Before each kinetic determination, the absorption spectrum in the Soret band of the experimental solution was recorded. The maximum was found to be at 421 mµ, as in aqueous solution. After the stages of photolysis and recombination, the spectrum was again recorded. The experiment was accepted only when the height and the position of the Soret band were identical with those observed initially. In some rare cases the Soret band spectrum recorded after the experiment was reduced in height with the maximum shifted to lower wavelength (to 414 mµ in the extreme—these results were discarded). This shift was no doubt caused by the formation of HbO_2 from traces of oxygen in the solution, for the spectrum thus obtained corresponded to that of HbO_2 (in aqueous solution or in a mixture of methanol and water at −55° C when prepared as described, starting from HbO_2 and omitting dithionite). Spectral anomalies, when found, were limited to those stated above, and never proceeded to stages indicating denaturation.

The kinetics of formation of HbCO after controlled photolysis were followed at 421 mµ, the stages of photolysis and combination could be repeated a number of times with little or no effect on the time course of the combination reaction. The rates obtained (thirty-four tracings from fourteen independent experiments) were consistent and when analysed gave the following results.

After slight photodissociation (~10 per cent), the rate of formation of HbCO can be described by a second order rate constant for the whole reaction. The value of this constant, which we shall call l'_4, is found to be 7×10^{-3} M^{-1} sec^{-1} at −55° C. This is not far from what would be expected from Gibson's value of 6.9×10^{-6} at 19° C and activation energy (10 kcal) determined in aqueous solution. We are aware that factors other than temperature (that is chemical composition, organization and viscosity of the solvent) may play a part in determining the rates, but the agreement seems to show that, at least for this reaction, the secondary effects are not much involved. Bielski and Freed[7] obtained continuous and expected change of rates from water to aqueous methanol in the case of hydrolysis of substrates by chymotrypsin.

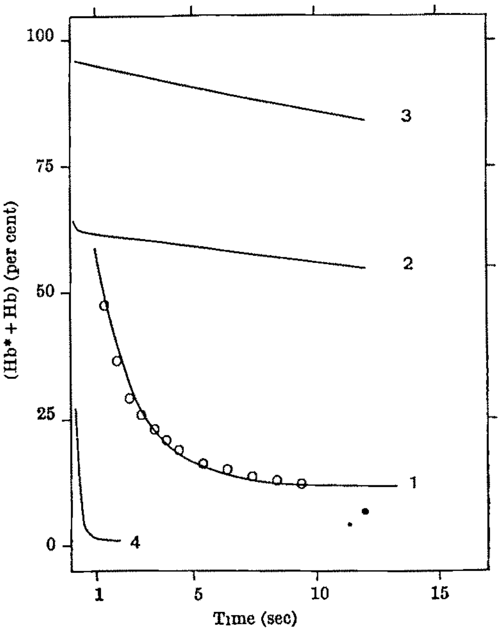

Fig. 1. Time course of formation of HbCO observed in a typical experiment at −55° C after high photodissociation. Solvent was 60 per cent methanol v/v containing *tris* buffer (*p*H 7.8 at 20° C). Initial concentration of HbCO was 2.6 µmolar (in haem), with 56 µmolar carbon monoxide. ○, Points read from the experimental tracing. Curve 1 was calculated following Gibson[4] but taking $l^* = 9.75 \times 10^3$ M^{-1} sec^{-1}, $l' = 1.91 \times 10^2$ M^{-1} sec^{-1}, $k_1 = 0.08$ sec^{-1}, assuming total photodissociation and all resulting haemoglobin initially to be the quick reacting form. Curve 2, expected time course with activation energies of (5.6 and 6 kcal for l^* ($l^* = 1.3 \times 10^5$ M^{-1} sec^{-1}) and k_1 ($k_1 = 11.9$ sec^{-1}) respectively. Curve 3, $l^* = 9.75 \times 10^{-3}$ M^{-1} sec^{-1} ($E = 11.1$ kcal), $k_1 = 11.9$ sec^{-1} ($E = 6$ kcal). Curve 4, $l^* = 1.3 \times 10^5$ M^{-1} sec^{-1} ($E = 5.6$ kcal), $k_1 = 0.08$ sec^{-1} ($E =$ 16.6 kcal).

Many of the uncertainties about the chemical and physical properties of the solvent should disappear when we consider the kinetics of the reaction at a given temperature (say −55° C) and compare the time course of formation of HbCO after slight photodissociation with that after high initial photodissociation. First, as said before, the reaction is strictly monophasic. After high initial photodissociation, the kinetics are heterogeneous, and can be fitted to Gibson's scheme in terms of the constants l^*, l' and k_1; in a typical experiment (Fig. 1), a good fit was obtained following Gibson's procedure[4] with $l^* = 9.75 \times 10^3$ M^{-1} sec^{-1}, $l' = 1.9 \times 10^2$ M^{-1} sec^{-1} and $k_1 = 0.08$ sec^{-1}. It is implied that the photodissociation is total and all the resulting haemoglobin is initially in the quick reacting form. These assumptions are justified from relevant logarithmic plots (not shown in the figure) which extrapolate at zero time to zero concentration of HbCO. While the value of l' agrees very well with that calculated from l' at 20° C and $E = 10.5$ kcal, those of l^* and k_1 are much smaller than what would be expected from activation energies and rate constants (at 1° C) reported by Gibson (Table 1). In the experiment reported in Fig. 1, the rapid phase lasted until about 9 sec, 8 sec after the recording was initiated. Values of l^* and k_1 consistent with the reported activation energies (5.6 and 6 kcal respectively)

Table 1 APPROXIMATE RATE CONSTANTS AND ACTIVATION ENERGIES DURING THE COMBINATION OF CARBON MONOXIDE WITH HUMAN HAEMOGLOBIN AT −55° C

Proportion of initial photo-dissociation	Rate constants	−55° C Solvent 60 vol methanol/40 vol water Found	Activation energy (kcal) Calc †	 Reported
Small	l'_4	$7\ 3 \times 10^3\ M^{-1}\ sec^{-1}$	11 6	10
High	l^*	$9\ 75 \times 10^3\ M^{-1}\ sec^{-1}$	11 1	5 6
High	l'	$1\ 9 \times 10^2\ M^{-1}\ sec^{-1}$	10 9	10 5
High	k_1	$0\ 08\ sec^{-1}$	16 6	6

The temperature was maintained at ±2° C Buffer salts (*tris*-) were present, but it seems impossible to give accurate *p*H values for the reaction media Some of these rate constants have been reported to vary with *p*H, but the difference in rates observed with solutions containing *tris* buffer at *p*H 6 7 or *p*H 7 8 was not larger than the experimental error The overall limit of error may be taken as about 1 kcal in terms of activation energies

† Calculated from rates at 19° C or 1° C reported by Gibson, and those observed during this work at −55° C

would have made the rapid phase disappear in 1 sec (curve 2) before we would have noticed it Likewise, it seems impossible to get a fit by assigning small values to either of l^* and k_1 separately (curves 3 and 4) Both of these rates seem to have a much greater temperature dependence than reported The value (11 kcal) we found for the activation energy of l^* seems to be in the expected range for a reaction of this rapidity involving gaseous ligand binding by haemoglobin[9]

The results show in general that gas binding by haemoglobin at −55° C in methanol and water is basically similar to binding in ordinary conditions It is agreeable to find evidence for haem-haem interaction, although there are no apparent reasons why this should not be so if the protein can be maintained in the native state On the other hand, these data may be considered in the light of recent work[5,6] on the identity of Hb* and the mechanism of its conversion to ordinary haemoglobin The quick reacting form has been suggested to consist of isolated chains in their monomeric form, with the deactivation step ($Hb^4 \rightarrow Hb$) simply the combination of deoxy α and β chains to give α β or $\alpha_2\ \beta_2$. We do not propose at this stage that our data bear on these considerations, but it is significant that the combination of ligand-free α and β chains to form α β or $\alpha_2\ \beta_2$ has been found by Antonini *et al* [11] to be very temperature dependent ($Q_{10} = 3\ 13$)

Radio Emitting Electrons in the Galaxy and the Solar Modulation of Cosmic Rays

by

India

The energy spectrum of electrons in interstellar space needed to explain the Galactic background radio emission has been derived. Information can then be deduced about the solar modulation of cosmic ray electrons.

A WIDE variety of observations, including measurements on heliocentric cosmic ray intensity gradients[1], has now established that even during the time of minimum activity of the Sun in its 11 yr cycle, there remains an appreciable residual modulation of the nucleonic components of the cosmic radiation These observations have prompted many attempts to understand the mode and magnitude of the solar modulation suffered by the nucleonic component existing in the near interstellar space, particularly within the framework of the solar wind model originally suggested by Parker[2] Such studies have revealed the following observational characteristics for the period of solar minimum which are now generally accepted by workers in this field (1) At rigidities, *R*, greater than 5 to 10 BV there seems to be very little or no modulation (2) For rigidities between about 0 5 BV and about 5 BV the modulation function $\exp(-K(t)/R\beta)$, where *K* is a time dependent constant and β is the ratio of the particle velocity to the velocity of light, can best represent the observations with a value of $K \approx 0\ 4$ to 1 0 BV (refs 3 to 5) (3) For lower rigidities the observational data suggest that the modulation is β dependent[1,6,7].

On the other hand, because the first experimental observations for a finite flux of cosmic ray electrons[8,9] were reported only in 1961, adequate electron flux measurements over a long enough period of time are not available, as in the case of the nucleonic component, to enable us to deduce, in a similar manner, information on the solar modulation of electrons As an important consequence of this, our present knowledge on this subject is in a rudimentary and, to some extent, controversial state[10–12] Nevertheless, information about electron modulation is very important because a comparison of the modulation suffered by electrons and nuclei will allow us to distinguish between contributions caused by rigidity and velocity dependent modulation, and thus lead to definitive conclusions regarding the mechanism of solar modulation It is now well recognized that cosmic ray electrons existing in Galactic space are responsible for the background radio emission; we have in the present treatment taken advantage of this special feature to infer directly the electron spectrum in interstellar space needed to account for the observed background radio spectrum We then compare this electron spectrum with that observed near the Earth during the period of minimum solar modulation, to draw valuable information on the nature of the modulation of electrons

In Fig 1 are summarized the data available on the differential flux of cosmic ray electrons[13–16] measured in the neighbourhood of the Earth near the time of minimum solar modulation (1965–66) It is seen that sufficient data exist for this period to construct a reliable energy spectrum from about 100 MeV to about 50 BeV;

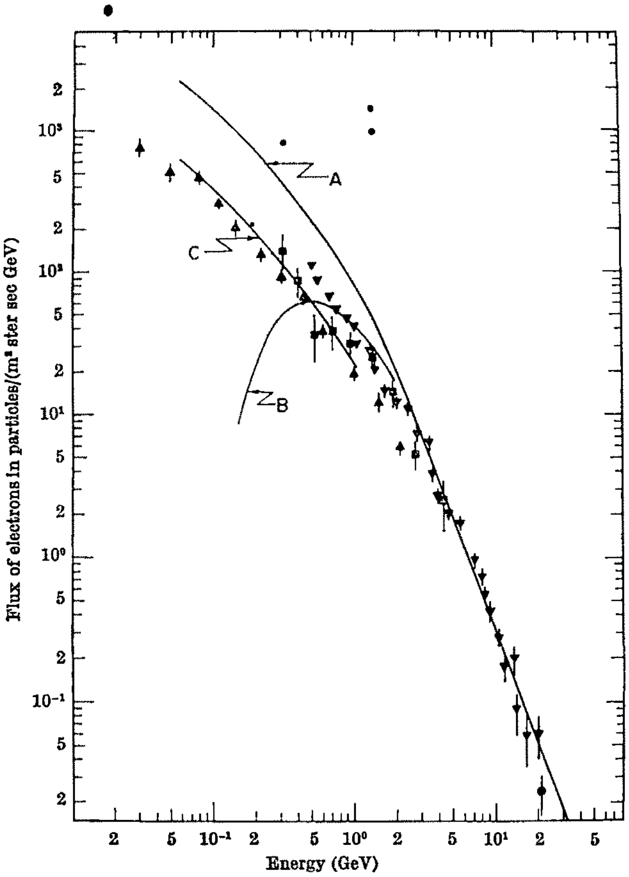

Fig 1 All data points refer to experiments made during 1965–66 except the highest energy point[15] Curve *A* is the electron differential energy spectrum derived for the near-interstellar space Curves *B* and *C* are the modulated spectra expected near the Earth from an *R* or *Rβ* dependence between 0 5 and 5 BV and a constant or a *β*-dependence below 0 5 BV respectively ▲, Beedle and Webber[16], ▼, Bleeker *et al* [18], ■, L'Heureux[14], ●, Daniel and Stephens[15]

it is also seen that the data above 5 BeV can be well fitted by the power law energy spectrum

$$\frac{\mathrm{d}J(E)}{\mathrm{d}E} = 126\, E^{-2.6 \pm 0.1}\ (\mathrm{m}^2\ \mathrm{sec\ ster\ BeV})^{-1} \qquad (1)$$

We would like to point out here that present evidence[17] strongly suggests that for rigidities in the range of 10 to 50 BV, the hydrogen, helium and heavy nuclei of the cosmic rays observed near the Earth all have power spectra with exponents Γ close to 2 6

From the many radio surveys made of the sky using wide angle beams, we have been able to construct the radio brightness distribution as a function of frequency for three general Galactic directions, namely, the Anticentre ($l'' \approx 140°$–$190°$ and $b'' \approx 10°$ N –10° S), the Galactic radio minimum (right ascension ≈ 10 h and $\delta \approx 20°$–$60°$) and the North Halo, but clearly avoiding the north polar radio spur (right ascension ≈ 10–17 h and $\delta \approx 30°$–$60°$) In addition, using narrow angle beam surveys, we have also been able to obtain the brightness distribution in the direction of the Galactic Ridge ($l'' = 0$ and $b'' = 3\ 6°$ N and 3 6° S) Details on the compiling of the radio and electron data and how they have been used to draw a number of meaningful conclusions regarding the electrons, and in general cosmic rays and magnetic fields in the Galaxy, are described in a separate paper[18] For purposes of the present analysis we have employed the radio spectra obtained for the direction of the Anticentre and the North Halo only; these are summarized in Fig 2 While constructing the radio spectrum for the Halo we have included data for only the northern Galactic hemisphere[19–24] because of the fact that the solar system is situated significantly above the Galactic plane, this helps in minimizing, in this direction, the contributions from the Galactic Radio Disk It may be seen from Fig. 2 that the observational data have been plotted only up to 10 MHz, below which Galactic absorption and other effects become progressively important It is also seen that the absolute sky brightness at 10 MHz in these two directions is nearly the same, with power index α in both cases close to 0 3–0 4 at low frequencies, slowly increasing to about 0 8 at the highest frequencies The value of $\alpha \approx 0\ 8$ at high radio frequencies can also be seen to be consistent with the power index of the high energy cosmic ray electrons (equation (1)) as expected from synchrotron mechanism.

Beginning with the first attempt in 1960 by Biermann and Davis[25], many investigators have used the background radio emission in the direction of the Galactic Halo to deduce information on the magnetic fields existing therein Okuda and Tanaka[26] have recently carried out such an analysis for the Galactic Centre and Anticentre In all these attempts, the simplified assumption is made that the observed radio emission and the radiating electrons have power law spectra connected by the relation $\alpha = (\Gamma - 1)/2$ Calculations are then carried out for the radio emission at a convenient frequency with an assumed electron spectrum made to fit the electron intensities observed near the Earth at some suitable electron energy Unlike these attempts, in what follows we derive the complete spectrum of radio emitting electrons (100 MeV to 10 BeV) needed to explain the observed radio emission (which is not a power law spectrum) in the frequency range of 10 to 400 MHz

Because we are primarily interested here in obtaining the electron spectrum as it exists in the near-interstellar space, we have chosen for the present analysis the Galactic Radio Disk in the direction of the Anticentre as resembling closest the near-interstellar space The dimension of the radio disk in this direction is thought to be reasonably well known and has a value of ≈4 kparsec Also, it seems reasonable to expect that the shape and intensity

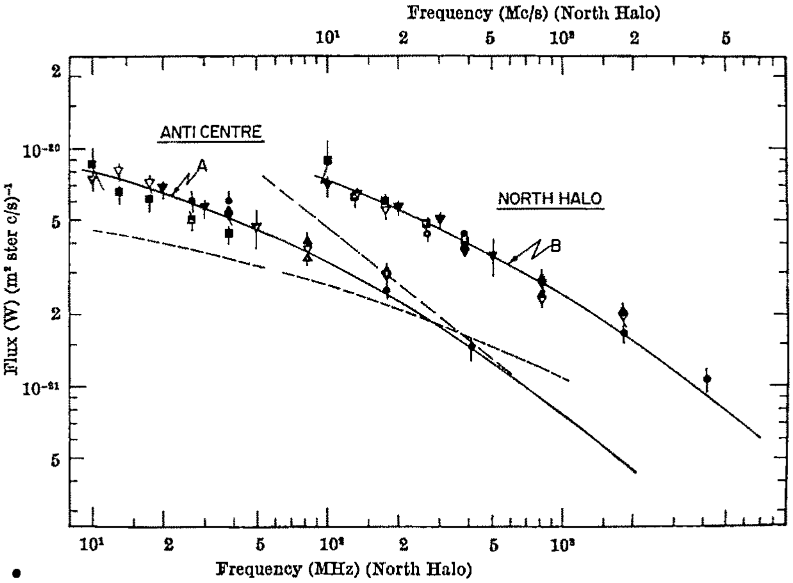

Fig 2 Radio brightness distributions in the directions of the Galactic Anticentre and North Halo Curve *A* for Anticentre and curve *B* for the North Halo were obtained using the electron spectrum *A* of Fig 1 - - -, Expected radio spectrum if experimental electron spectrum of Fig 1 and $\langle H_\perp \rangle = 7 \times 10^{-6}$ gauss are used, — — — —, expected radio spectrum if the power law electron spectrum given by equation (1) extending down to 100 MeV and $\langle H_\perp \rangle = 5 \times 10^{-6}$ gauss are used ◆, Costain[24], ●, Turtle *et al* [19], ▼, Parthasarathy and Lerfald[20], ■, Andrew[21], ▲, Purton[22], △, Bridle[23]

of electrons above 5 GeV are well preserved in the interstellar space as there are known to be in the case of the nucleonic component Thus we first attempt to deduce the electron spectrum in the interstellar space below 5 BeV by making use of the radio spectrum towards the Anticentre and later show that such a spectrum, if it exists in the Halo, would also be able to explain the observed radio spectrum in this direction

It is appropriate to mention briefly here the effect, in the present analysis, of any isotropic metagalactic radio component that may exist Though many attempts have been made by radio astronomers to estimate the magnitude of such a component, the situation is still far from satisfactory It is generally thought, however, that its contribution is likely to be $\lesssim 20$ per cent of the Galactic background emission The influence of this component, even if it exists to the extent of 20 per cent, on the derived electron spectrum depends on the assumed shape of the metagalactic radio spectrum and it can be easily shown[18] that in any case its effects are small and will not alter any of our general conclusions For this reason we have neglected in the present analysis the effects, if any, caused by the metagalactic radio component and hence all observed background radio emission has been attributed as being of Galactic origin

We will now proceed to describe the method of determining the electron energy spectrum responsible for the Galactic background radio emission The intensity of the synchrotron radiation at a frequency ν emitted along the line of sight by radiating electrons having a spectrum of energies can be written as[27]

$$I_\nu = \frac{\sqrt{(3)}e^3 < H_\perp >}{4\pi mc^2} L \int_{E_1}^{E_2} G_\nu (E)\, N(E)\, \mathrm{d}E \tag{2}$$

where $< H_\perp >$ is the mean component of the magnetic field perpendicular to the line of sight in the radiating region, L is the radiating distance along the line of sight

$$G\nu(E) \equiv x \int_x^\infty K_{5/3}(\eta)\mathrm{d}\eta \tag{3}$$

through the relation

$$x = \frac{\nu}{\nu_c} = \frac{4\pi mc}{3e < H_\perp >}\left(\frac{mc^2}{E}\right)^2$$

and $N(E)\,\mathrm{d}E$ is the number of electrons per unit volume with random directions of motion and having energies in the interval E and $E+\mathrm{d}E$ (all notations used here are the same as in ref 27) The limits of integration E_1 and E_2 are chosen such that

$$G_\nu (E_1)\, N(E_1)\, \mathrm{d}E \approx G_\nu (E_2)\, N(E_2)\mathrm{d}E \lll [G_\nu(E)N(E)\mathrm{d}E]_{\max}$$

The value of $[G_\nu(E)N(E)\mathrm{d}E]_{\max}$ would depend on the spectral shape of the electrons and can be estimated suitably For a radio spectrum which is not a simple power law, as is the case in Fig. 2, the electron spectrum required to give rise to it can best be obtained by a method of trial and error

Of the two free parameters L_A and $< H_\perp >_A$ relevant to the Anticentre, the former was assumed to be 1 25 × 10^{22} cm Because it has also been assumed that electrons with $E_e > 5$ BeV in the radiating region have the same spectrum as in the vicinity of the Earth, it is possible to set quite meaningful constraints on $< H_\perp >_A$ because it has to be such that the electron spectrum deduced for lower energies smoothly joins with that at energies > 5 BeV near the Earth It may also be pertinent to stress here that the fitting in the high frequency end of Fig 2A depends primarily on the assumed magnetic field because in this frequency region $I_\nu \propto L - < H_\perp >^y$, where $y > 1$ It is then possible by trial to fix a single value of $< H_\perp >_A$ and a unique, smoothly varying electron spectrum to match the observed radio spectrum The electron spectrum shown by curve A in Fig 1 and a value $< H_\perp >_A = 5 \times 10^{-6}$ gauss are thus obtained corresponding to the solid curve shown in Fig 2A for the radio brightness spectrum It is expected that any uncertainty in the electron spectrum derived for the interstellar space (curve A of Fig 1) will primarily result from uncertainties associated with the radio observations It is now interesting to notice that if we assume the same electron spectrum deduced for the Anticentre (curve A of Fig 1) to exist also in the Halo region, we get an exceedingly good fit (solid curve in Fig 2B) with $L_H = 4 \times 10^{22}$ cm and $< H_\perp >_H = 2 \times 10^{-6}$ gauss We therefore conclude that the electron spectrum given by curve A in Fig 1 represents the spectrum of electrons as they exist in the near-interstellar space, this may also be the case in the Galactic Halo.

We now proceed to compare curve A in Fig 1 representing the electron spectrum deduced for the near-interstellar space with that observed near the Earth in 1965–66 and deduce information on the electron modulation Such a comparison reveals the following important features (a) between about 0 5 BV and 5 BV, the modulation can be described equally well by an $R\beta$ or R dependence with a value for the constant $K \approx 0$ 65 (expected shape near Earth is then given by curve B of Fig 1), and (b) for $R < 0$ 5 BV there is a constant modulation which can also be understood as β dependent with a value for the constant $K \approx 1$ 3 (expected shape near Earth is then given by curve C of Fig 1) It is seen that inferences (a) and (b) are also consistent with our knowledge of the nucleonic modulation summarized early in this article We would further like to mention that the residual solar modulation of electrons in the entire energy region 0 1 BV to 5 BV can be represented well by a single modulation function of the form $\exp[-K/(a+R)\beta]$ where K and a are constants with values of $K \approx 1$ 4 and $a \approx 1$ because $\beta \approx 1$

We acknowledge with gratitude the many useful suggestions and comments made by colleagues from this institute

Discrete Potentials in the Dark-adapted Eye of the Crab *Limulus*

by
JOHN E. DOWLING
Wilmer Institute,
Johns Hopkins University School of Medicine,
Baltimore, Maryland,
and
Marine Biological Laboratory,
Woods Hole, Massachusetts

Two types of discrete depolarizing potentials are recorded intracellularly from thoroughly dark-adapted visual cells of small *Limuli* stimulated with dim light. The larger type of discrete potential seems to be associated with the generation of nerve impulses in the eye in these conditions.

One of the striking discoveries made by intracellular recording from visual cells in *Limulus* was of small, discrete, depolarizing potentials which appear on stimulation with dim light or, occasionally, spontaneously in darkness[1]. In the first reports of such potentials, it was suggested that they are responses to single quantum absorptions, and so they were given the name "quantum bumps"[1,2]. Later studies showed that a second, larger type of discrete potential can often be elicited from the visual cells in *Limulus*, particularly when the cells are slightly hyperpolarized[3,4]. This second type of discrete potential is frequently superimposed on a quantum bump or other small depolarization of the cell membrane and is usually several times larger in amplitude. It has been suggested therefore that the large discrete potentials are a type of non-propagated regenerative response that arises in the visual cells in certain conditions[3-6].

The contribution of the two types of discrete potentials, particularly the regenerative responses, to the generator potential of the ommatidium and to the generation of nerve impulses in the eye has not been clarified. This report describes some intracellular recordings obtained from the ommatidia of thoroughly dark-adapted small *Limuli* which show very clear and large discrete potentials. The recordings also suggest a role for the regenerative responses in the dark-adapted eye.

Lateral eyes from small *Limuli* (3–4 in across the carapace) were excised and clamped firmly by an attached piece of shell in a small chamber containing sea water. The eyes were sliced approximately in half, with a razor blade, to expose intact ommatidia. White light from a microscope illuminator was focused through the cornea on to a single exposed ommatidium. The time of illumination was controlled by mechanical shutters, and light intensity by neutral filters inserted in the beam. A micropipette filled with 2 molar KCl and with a resistance varying from 30 to 70 megohms when measured in sea water was inserted into the ommatidium with the aid of a micromanipulator. Ag–AgCl electrodes connected the micropipette and chamber to a Keithley negative-capacitance electrometer. The amplified responses were displayed on an oscilloscope and recorded photographically.

The successful penetration of a cell was signalled by a sudden negative shift of the micropipette and the appearance of large positive responses to light stimuli. In this study, only cells showing large resting potentials (usually 70–90 mV) and large generator potentials (80–120 mV for retinular cells) were used. Numerous cells with lower resting and generator potentials (30–50 mV) were encountered. These cells were usually 1–2 log units less sensitive to light and did not show large discrete potentials, and so they were not carefully studied. The experiments were carried out at room temperature (25°–27° C), and after a satisfactory cell had been penetrated, the preparation was left undisturbed in the dark until it was thoroughly dark adapted. This took at least 30 min.

Two distinct types of response to moderate or bright light stimuli are encountered after penetration of a cell of the *Limulus* ommatidium[7]. The first type of response is a smooth depolarization, consisting of an initial transient wave and a steady potential which is maintained for the duration of the light stimulus. A notch is occasionally observed on the ascending portion of the transient wave, which suggests that there is also an initial spike-like component in the response[6,8]. The second type of response consists of a similar but smaller depolarization on which large nerve impulses are superimposed. The current interpretation of these responses is that the smooth depolarizing potential is a generator potential, which originates in the rhabdom region of the retinular cells and spreads by electrotonus into an eccentric cell, where it generates nerve impulses[9-12]. In support of this view is evidence that retinular and eccentric cells are electrically coupled[13]. The large, smooth depolarizing potentials are therefore believed to derive from the retinular cells, and the responses with superimposed impulses are thought to come from the eccentric cells. There are between ten and fifteen retinular cells in an ommatidium and usually one eccentric cell[14]. Thus in random penetrations, responses of retinular cells are encountered very much more frequently than are responses of eccentric cells.

Typical responses of a fully dark-adapted retinular cell to graded intensities of light are shown in Fig. 1. In the dark, such cells often show little spontaneous activity. Distinct responses to light are first detected when the light stimulus is attenuated about 7 log units. These initial responses consist of two types of discrete potentials. The first type is a regular, wave-like potential, 4–8 mV in size, which occurs repetitively during a prolonged threshold stimulus. The individual waves often appear in groups and summate to give a more sustained depolarization of the cell. The second type of discrete potential occurs less frequently. In Fig. 1, for example, only one such potential is observed with the threshold stimulus. These potentials are very large (up to 60 mV) and their shape, particularly their peak, is much sharper than that of the smaller potentials The small type of potential is believed to be the previously described quantum bump[1,2], while the large type of discrete potential is probably a regenerative response[3,4] This terminology will be adopted here, although the present experiments have little to add concerning the accuracy of these designations

With somewhat brighter stimuli (6 log unit attenuation of the light stimulus) a small but steady depolarization of the cell lasts for the duration of the stimulus (From inspection of the tracings in Figs 1–3, it seems likely that the small sustained depolarization in response to dim light is caused simply by summation of numerous quantum bumps) Superimposed on the sustained depolarization are several regenerative responses These regenerative responses are quite similar in size and shape, and resemble the single regenerative response observed with the dimmer (threshold) stimulus With yet brighter light stimuli, greater sustained depolarization is observed; and it is no longer possible to recognize either individual quantum bumps or regenerative responses. With progressively brighter stimuli, the responses become increasingly smooth until (with 2 log unit attenuation of the stimulus beam) an entirely smooth generator potential is observed

Thus only with dim light stimuli are the quantum bumps and regenerative responses easily distinguished Additional records illustrating the two types of discrete responses are shown in Fig 2 The regenerative responses are usually observed arising from the top of one or a group of quantum bumps Occasionally, a regenerative response seems to arise independently of the quantum bumps (Fig 3) This is difficult to judge, however, because if a quantum bump and a regenerative response superimpose closely, the underlying quantum bump would not be obvious

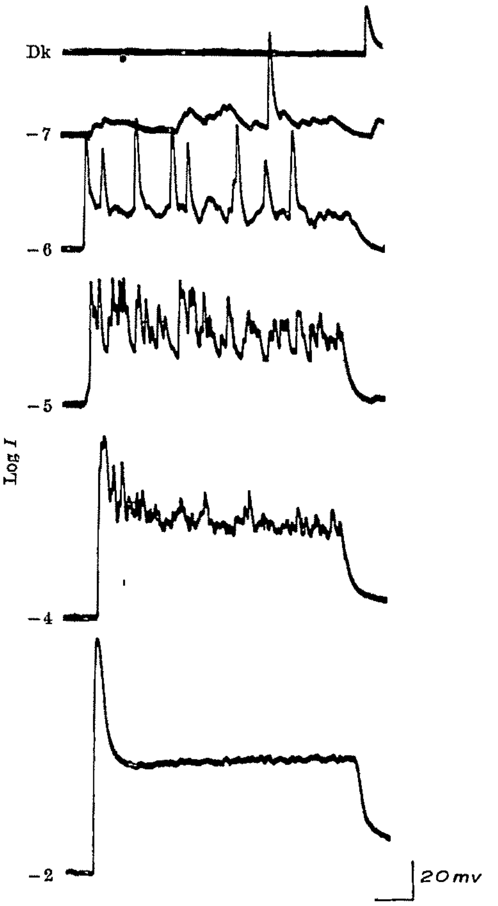

Fig 1 Responses of a thoroughly dark-adapted retinular cell to graded intensities of light. The numbers to the left of each record indicate the stimulus attenuation in log units The bar below the record indicates the approximate duration of the light stimulus See text for details

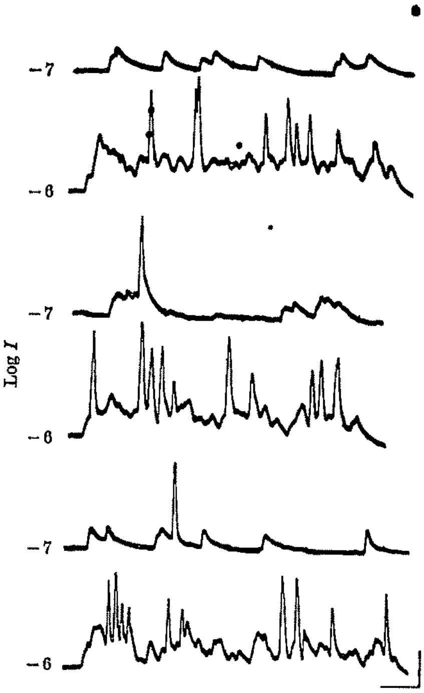

Fig 2 Responses of a retinular cell to dim illumination (7 and 6 log unit attenuation of the stimulating beam) These records show clearly the two types of discrete potentials elicited from the dark-adapted cell Vertical calibration, 20 mV, horizontal calibration, 0 5 sec

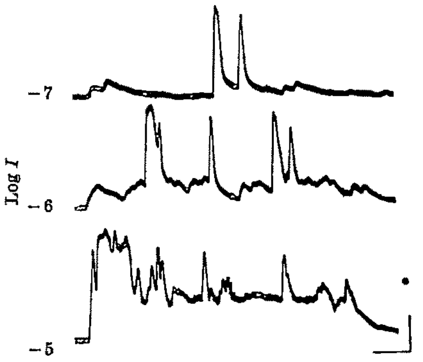

Fig 3 Responses of a dark-adapted retinular cell to graded intensities of light, showing decreasing latency of first regenerative response with increasing intensity Calibration as in Fig 2

One feature of the responses of retinular cells to moderate and bright light which was noted previously is the presence of a notch on the leading edge of the generator potential[6,8] This notch may be caused by a single regenerative response which occurs initially after stimulation of the dark-adapted eye with moderate or bright light A record suggesting this is shown in Fig 3; all three tracings in the record show regenerative responses of similar size and form With brighter stimuli, however, the first regenerative response appears earlier, until it is observed preceding most of the sustained depolarization In the bottom tracing in Fig. 3 the initial regenerative response is also the largest and clearest, suggesting, perhaps, that full-sized regenerative responses are elicited only for a narrow range of membrane polarization This may

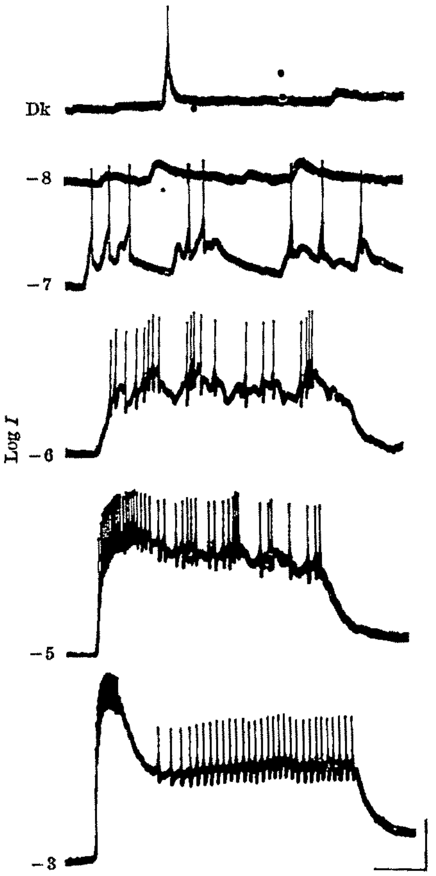

Fig 4 Responses of a thoroughly dark-adapted eccentric cell to graded intensities of light See text for details Calibration, 20 mV and 0 2 sec

explain why only one regenerative response is ordinarily observed after stimulation of the eye with moderate or bright light

It was assumed that an eccentric cell had been penetrated when impulses of 15–60 mV were observed superimposed on the generator potential Occasionally, small impulses are detected in retinular cell recordings, but the amplitude of these impulses never exceeds 1–5 mV. In records from retinular cells that show large discrete potentials, impulses are not usually observed (Figs. 1–3).

As already noted, generator potentials observed in eccentric cell recordings are usually smaller than the generator potentials noted in retinular cell recordings The discrete potentials are also smaller in eccentric cell recordings and thus cannot be distinguished as readily as in retinular cell recordings Nevertheless, in many recordings from eccentric cells, especially when the impulses are not very large (15–30 mV), discrete potentials of two varieties can be observed

A set of responses of one such eccentric cell to stimuli of increasing intensity is shown in Fig 4 In the dark, this cell showed an occasional spontaneous discrete potential and nerve impulse The first responses to dim light (log $I = -8$) consisted of small waves of depolarization These waves vary considerably in size and duration, suggesting that they are not single quantum bumps but probably groups of summating bumps, similar to the quantum bumps of varying size observed in retinular cell records (compare Figs 1 and 4)

With brighter stimuli (log $I = -7$) a more sustained depolarization of the cell is observed Superimposed on the sustained depolarization are sharp, discrete potentials which seem similar to the regenerative responses seen in retinular cell recordings. Nerve impulses are also seen in the record and are associated with each of the regenerative-like responses

With still brighter stimuli a greater sustained depolarization is evoked, and regenerative-like responses are more difficult to detect and to associate with the numerous impulses The brighter the light stimulus, the smoother is the generator potential and the more regular is the discharge of impulses. The responses of eccentric cells shown in Fig. 5 are about 1 log unit more sensitive than the comparable responses of the retinular cell shown in Fig 1 This is the usual finding, and it probably reflects the summated effects of the ten to fifteen retinular cells on the single eccentric cell of an ommatidium

In Fig. 5*a* the close relation between the regenerative-like responses and the impulses in the eccentric cell is shown more clearly. In all these records, impulses are observed only in conjunction with regenerative-like responses. For example, with 7·5 log attenuation of the stimulating beam, a very small sustained depolarization was observed together with five clear and prominent regenerative-like responses. Five impulses are seen in Fig 5*a*, superimposed on the five regenerative-like responses In Fig. 5*b*, recorded at a much faster sweep speed, one such regenerative-like response is shown with superimposed impulse The impulse has a duration of about 4 msec; the regenerative-like response, about 100 msec The regenerative-like response has a smooth wave-form, interrupted only by the impulse.

The regenerative responses, in occurring repetitively in an all or none fashion when elicited with a prolonged dim light, have characteristics similar to those of nerve impulses. It is known that tetrodotoxin blocks the transient influx of sodium ions that occurs when a nerve impulse is generated but does not appreciably affect slow, generator-type potentials[15].

In Fig 6 the effect of tetrodotoxin on the nerve impulses, quantum bumps, and regenerative responses of the photoreceptor of *Limulus* is shown The concentration of tetrodotoxin used in these experiments was 2×10^{-6} g/100 ml of sea water. Within 3 min of infusion of the drug, impulses are blocked in the eye and remain blocked as long as the drug is present. When the drug has been washed away, nerve impulses reappear, but if the con-

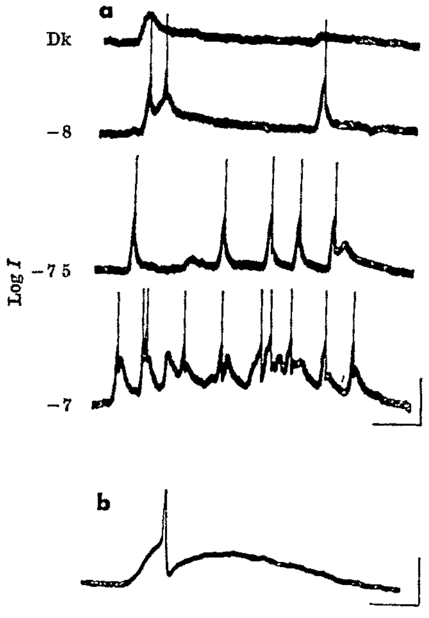

Fig 5 *a*, Records from an eccentric cell showing the close relation of the regenerative-like potentials and nerve impulses in the dark-adapted eye stimulated with dim light Calibration, 20 mV and 0 2 sec *b*, Regenerative-like response with superimposed impulse, recorded at fast sweep speed Vertical calibration is same as Fig 5*a*, horizontal calibration, 20 msec

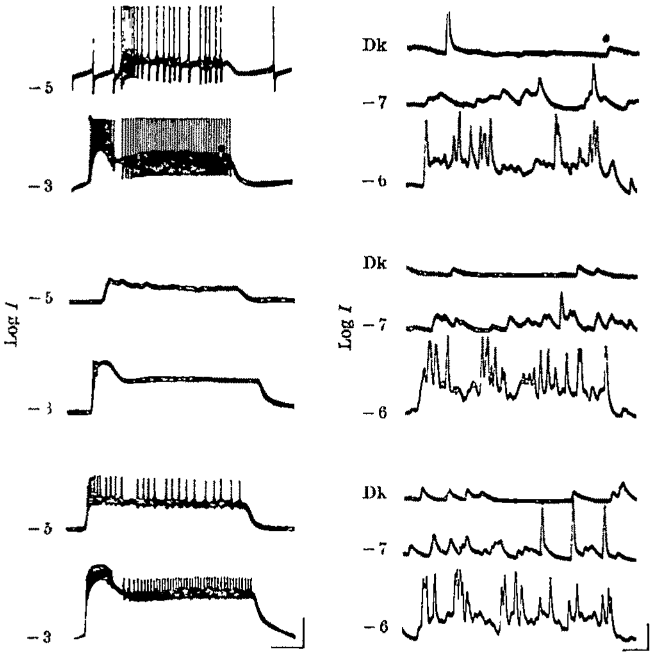

Fig 6 Effect of tetrodotoxin on the nerve impulses of eccentric cell (left) and on quantum bumps and regenerative responses of retinular cell (right) The top tracings are the controls recorded before addition of the drug Middle tracings are responses recorded 10 min after infusion of the drug, and bottom tracings are responses recorded 20 min after start of sea water wash The impulses are abolished by tetrodotoxin, but the quantum bumps and regenerative responses are unaffected Drug concentration was 2×10^{-6} g/100 ml Vertical calibration, 20 mV, time calibration 0 2 sec on left, 0 5 sec on right

centration and duration of the drug exposure were high, as here, only partial recovery of the impulse amplitude is noted.

No effects on either the quantum bumps or regenerative responses are observed after exposure of the eye to the same concentration of tetrodotoxin that rapidly eliminates the nerve impulses. So far, I have not observed tetrodotoxin to affect any component of the generator potential Benolken and Russell have reported some effects of tetrodotoxin on the generator potential in *Limulus*, but the concentration of tetrodotoxin they used was 5 to 1,000 times greater than was used here[8]

Recordings from thoroughly dark-adapted retinular cells show two types of discrete potentials clearly Recordings from eccentric cells are somewhat more equivocal because the discrete potentials are smaller, but in many instances two types of discrete potentials can be recognized which seem to correlate with the discrete potentials of the retinular cells The present experiments indicate that the discrete potentials observed in the eccentric cell originate at some distance from the impulse-generating site, because in those recordings that show large nerve impulses the discrete potentials (and the rest of the generator potential) are small, and vice versa These observations therefore suggest that the discrete potentials (like the rest of the generator potential) originate in the retinular cells and spread electrotonically into the eccentric cells

When the dark-adapted ommatidium is stimulated with dim light, the generation of nerve impulses seems to be correlated with the presence of regenerative responses. With brighter light stimuli, regenerative responses are not clearly recognized, but the sustained depolarization induced by the light is large and apparently sufficiently large to generate impulses in the eccentric cell. It is therefore tempting to suggest that the regenerative responses provide the potential to generate action potentials in the dark-adapted eye, when too few quanta are absorbed to provide sufficient sustained depolarization to induce action potentials It has long been realized that visual systems, including that of *Limulus*, can be excited by very few quanta[7,16] If, however, the small discrete potentials observed in retinular cell recordings are the quantal responses, it seems unlikely that only a few such quantum bumps could provide sufficient depolarization to generate an impulse at the spike generating site in the eccentric cell, which is perhaps several hundred microns away The regenerative responses may be, therefore, the amplification mechanism by which action potentials are elicited in the dark-adapted eye when only a few quanta are caught To confirm these ideas it will be important to make recordings from retinular cells and optic nerve simultaneously, to show unequivocally the correspondence of regenerative responses in the retinular cells and impulses in the optic nerve

The regenerative responses are interesting potentials that warrant further study In the dark-adapted eye these potentials are large (up to 60 mV), quite constant in size and shape, and are evoked repetitively in dim light They are not affected by tetrodotoxin, but are profoundly reduced in amplitude by light adaptation. A single bright flash will eliminate them, and 15 min or more in the dark is often necessary before they recover their initial amplitude These responses seem to be regenerative, but they probably do not propagate, because they are usually smaller when recorded in the eccentric cells Thus they share properties of both slow, graded potentials and nerve impulses

The final point concerns the conditions in which discrete potentials, especially regenerative responses, are best seen. Four factors seem to be important These are (*a*) the use of small (3–4 in) *Limuli*, (*b*) thorough dark-adaptation of the preparation (30 min at 25°–27° C), (*c*) the use of relatively fine micropipettes (30–70 megohm resistance in sea water), and (*d*) the use of cells with large resting potentials and large generator potentials Although on several occasions one or more of these factors have varied and good discrete potentials have still been observed, the best recordings have invariably been made with these conditions fulfilled It also seems likely that the micropipette must be in a particular location in the cell, perhaps close to the rhabdom region, if large discrete potentials are to be observed On one or two occasions, a slight shift of the pipette during an experiment significantly changed the size of the discrete potentials but did not appreciably affect the resting potential This suggests that the pipette did not withdraw from the cell, but simply moved within the cell to a new position, one that was more (or less) advantageous for recording the discrete potentials

I thank E F MacNichol, jun , for lending equipment, for helpful advice, and for reading the manuscript. H Grundfest provided the tetrodotoxin This investigation was supported by the US Public Health Service and by Research to Prevent Blindness, Inc

Detection of an Anisotropic Soft X-ray Background Flux

by
C. S. BOWYER
G. B. FIELD
J. E. MACK
Department of Astronomy and
Space Science Laboratory,
University of California, Berkeley

The cosmic X-ray background has been found to be anisotropic. It is interpreted as being made up of two components: an isotropic background, possibly of extragalactic origin, and an anomalous emission, perhaps located within the Galaxy.

On December 13, 1966, at 06.30 UT, an instrumentation package carrying several X-ray detectors was launched on an Aerobee 150 rocket from Natal, Brazil. The X-ray background observed in the 44–70 Å band on the flight was anisotropic and is interpreted to consist of an extragalactic component and a component which may possibly be associated with the galactic corona.

The instrument which supplied the data reported here was a proportional counter with an effective collecting area of 500 cm². The detector was collimated to 8° full width half maximum (FWHM) by a honeycomb collimator. A constant pressure gas flow system was used to ensure stable operation of the counter throughout the flight. The pressure regulator employed was capable of holding the preset counter pressure to better than 0.1 per cent. Counting gas was continuously flushed through the counter through an umbilical before the launching. After lift-off, flow was maintained from an onboard gas supply bottle.

A calibration detector with an internal iron-55 source was connected in parallel with the primary detector and shared the high voltage and counting gas of the detector. The electronics chain servicing the primary detector was switched to the calibration detector periodically throughout the flight to check the overall system gain. These calibrations indicated that the primary detector was stable to the limit of readability of the data or to better than 0.2 per cent.

The window employed in the detector was nominal 1/8 mil 'Mylar' with a 200 Å 'Nichrome' coating. The counting gas was 90 per cent argon and 10 per cent methane. A laboratory calibration of the transmission of the window was made at 7 Å and 44 Å. The detection efficiency of the counter is shown in Fig. 1. The data from the detector were amplified and fed to an eight-channel pulse height analyser. The output from each channel was then telemetered to ground.

The rocket was despun at 70 km to a roll period of 12 sec by a gas despin mechanism. As the rocket spun and precessed, it scanned much but not all of the overhead sky. The determination of the rocket aspect as a function of time was greatly complicated by the failure of the onboard stellar photometers. An aspect solution was eventually obtained by combining the data from two onboard magnetometers with X-ray data from the proportional counters. The spin rate, precession rate, coning angle and the angle between magnetic north and the angular momentum vector were determined from the magnetometer data. A unique position sighting necessary to specify completely the solution was provided by a roll on which both the Crab Nebula and Sco*XR*-1 were observed by the X-ray detectors. These two sources were unambiguously identified by their intensities and by their angular separation.

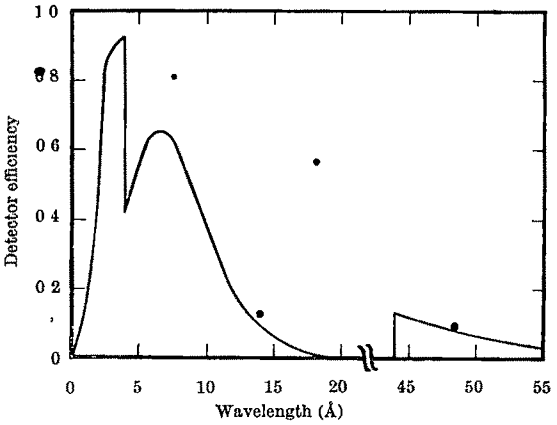

Fig. 1. Detector efficiency of the proportional counter. Photons producing counts in the 44–70 Å band were discriminated electronically and telemetered directly to ground.

Although this aspect solution does not possess the strong internal verification of a solution based on stellar signals, several checks on self consistency were available. The solution obtained was consistent with a rigid body solution based on the moments of inertia of the rocket and the observed roll rate. In addition, a strong source was observed approximately 100 sec before the Sco*XR*-1 sighting. The position of this source is within 10° of the reported location of Cen*XR*-2 (ref. 1).

From this aspect solution, the detector scans were plotted in galactic co-ordinates. Photons detected in the 44–70 Å band were handled in the following way. The celestial sphere was divided into elements of 50 square degrees, corresponding to the approximate resolution area of the collimator. The midpoints for all scans passing through a given resolution element were noted, and the number of photons detected in 0.5 sec about those points were averaged and recorded for that element. The photon count in each element was then reduced by a background count of 4 counts/0.5 sec. This counting rate was observed throughout the flight when the detectors were looking in the downward direction. The statistical validity of the count in each element varied from ±8 per cent to ±50 per cent depending on the number of scans and the number of counts/scan contributing to the average count in that element. Typically elements were valid to ±20 per cent.

A simplified version of this plot was superimposed on a map of the galactic hydrogen distribution taken from ref. 2, and is shown in Fig. 2. In this composite map, the photon counts are grouped into four intensity categories. A general trend is evident which shows that the count rate is higher near the pole than it is near the galactic equator.

The data from the higher energy channels have not as yet been completely analysed. As a preliminary step, however, the rate of counting uncorrected for detector efficiency was determined for the region within 20° of the galactic pole and the region within 10° of the galactic plane. These results, along with the 44–70 Å data, are given in Table 1. It is clear that the correlation rate of counting with galactic latitude is lost at higher photon energies in agreement with earlier work[3].

To interpret the data of Fig. 2, we have tentatively divided it into two components: (*a*) an intrinsically isotropic background, possibly extragalactic in origin, and

Table 1

Wavelength band	Galactic pole	Galactic plane	Ratio of plane to pole
	Counts/half sec		
44–70 Å	10±1	0·3±0·9	0·03±0·09
5–16 Å	26±1·4	22 ±2	0·85±0·09
3– 5 Å	14±1	18 ±2	1·29±0·17
2– 3 Å	9±1	10 ±2	1·11±0·25

(*b*) an anomalous emission in $300° < l < 30°$ and $b < 70°$, perhaps located within the Galaxy. The first component may be identified with the background detected at higher energies where the attenuation by interstellar gas is negligible. The fact that it correlates with latitude in the present experiment is interpreted as interstellar attenuation of an extragalactic source, an effect predicted by Gould and Sciama[4]. We have analysed the data to obtain the isotropic intensity corrected for attenuation and the magnitude of attenuation within the Galaxy.

This analysis is based on the relation

$$R = A\Omega \int_0^{\varepsilon_0} j(\varepsilon)\, E(\varepsilon)\, e^{-\tau(\varepsilon)}\, d\varepsilon \tag{1}$$

where R is the count rate, A is the detector area, Ω is the effective solid angle ($2·05 \times 10^{-2}$ ster), $j(\varepsilon)$ is the unattenuated photon spectrum at energy ε (quanta cm^{-2} sec^{-1} ster^{-1} keV^{-1}), $E(\varepsilon)$ is the detector efficiency and $\tau(\varepsilon)$ is the optical depth of the interstellar gas. The detector cut-off is at $\varepsilon_0 = 0·28$ keV, corresponding to 44 Å.

The optical depth τ equals σN_H, where σ is the effective cross-section per hydrogen atom and N_H is the atomic hydrogen column density based on 21 cm measurements[2]. In the present energy range, σ is caused entirely by hydrogen and helium, which are assumed to be neutral. The most recent calculations of σ yield[5]

$$\sigma = \sigma_0 \left(\frac{\varepsilon}{\varepsilon_0}\right)^{-b}$$

$$\sigma_0 = (0·84 + 21·4\xi) \times 10^{-21}\ \text{cm}^2 \tag{2}$$

$$b = 3·2,$$

where σ_0 is the effective cross-section at $\varepsilon_0 = 0·28$ keV, and $\xi = n(\text{He})/n(\text{H})$. We fitted E by $E_0(\varepsilon/\varepsilon_0)^c$, with $E_0 = 0·158$ and $c = 6·2$. Although $j(\varepsilon)$ is not yet known, we assumed a power law $j_0(\varepsilon/\varepsilon_0)^{-a}$, where $a \simeq 1·6$ from previous results below 100 keV (ref. 6). When these approximations are inserted into equation (1), the result can be written

$$R = R^0\, F(\sigma_0 N_H)$$

where

$$R^0 = \frac{A\Omega j_0 E_0 \varepsilon_0}{1 + c - a} \tag{3}$$

is the count rate outside the galactic disk and $\sigma_0 N_H$ is the optical depth (at 44 Å) for the direction in question. While $F(\sigma_0 N_H)$ can be evaluated exactly in terms of incomplete Γ functions, a sufficiently accurate approximation is

$$F = \exp(-1·47\sigma_0 N_H) \tag{4}$$

The count rates corrected for background were divided into eight groups according to the value of N_H at the observed position in the sky. Mean values of $R_{0·5}$ (counts/0·5 sec interval) and dispersions based on count statistics were computed. The results are presented as log $R_{0·5}$ against N_H in Fig. 3. (The point for $N_H > 1·6 \times 10^{21}$ is $1·2 \pm 0·3$ and is consistent with the data plotted.) The correlation between log $R_{0·5}$ and N_H is good, confirming the qualitative result from Fig. 2. The fit of a straight line (equations (3) and (4)) yields

$$R^0 = 2R^0_{0·5} = 22 \pm 3\ \text{c.p.s.}$$

and

$$\sigma_0 = (0·91^{+0·25}_{-0·14}) \times 10^{-21}\ \text{cm}^2$$

The errors quoted are estimates of the maximum permissible error. From equation (3), the corrected count rate corresponds to

$$j_0 = 270 \pm 40\ \text{quanta cm}^{-2}\ \text{sec}^{-1}\ \text{ster}^{-1}\ \text{keV}^{-1}\ \text{at } 0·28\ \text{keV}$$

or

$$J\nu = (5·1 \pm 0·7) \times 10^{-25}\ \text{erg cm}^{-2}\ \text{sec}^{-1}\ \text{ster}^{-1}\ \text{Hz}^{-1}$$

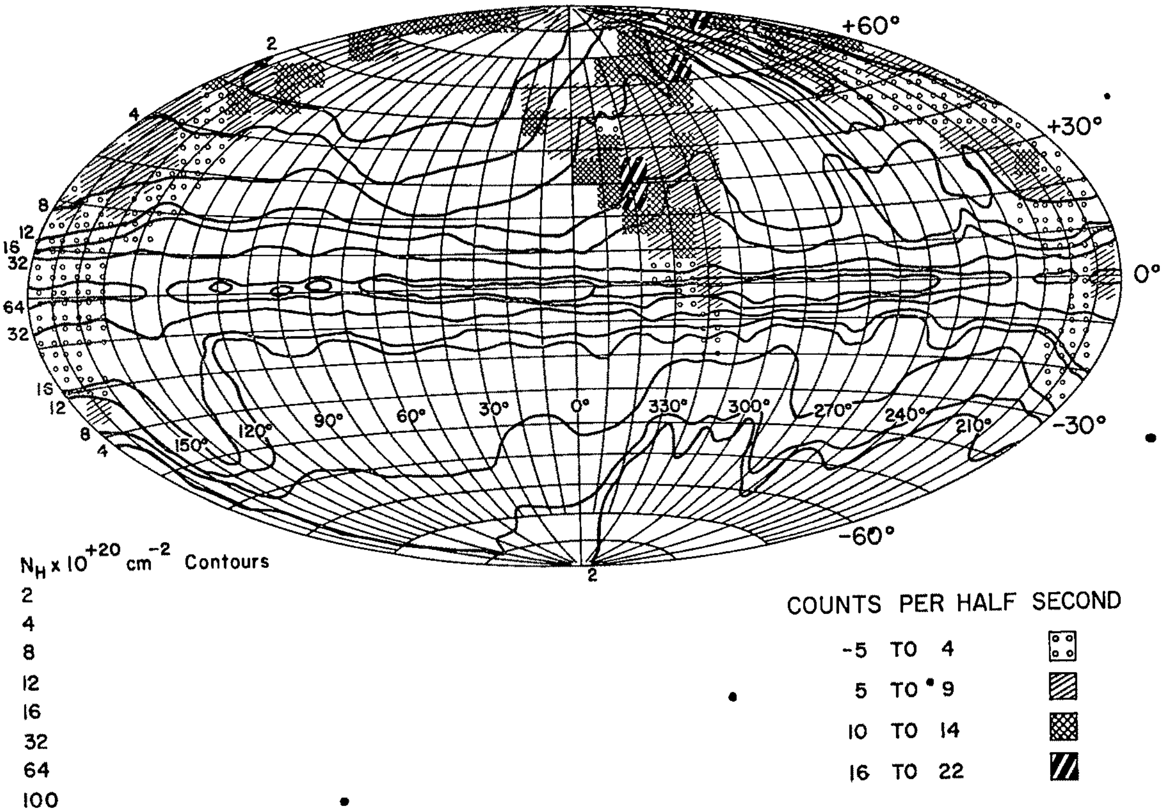

Fig. 2. 44–70 Å photon counting rates superimposed on a plot of the galactic hydrogen distribution. The resolution areas employed correspond to the effective resolution area of the collimator and the count rates refer to 0·5 sec averages.

The cross-section σ_0 inferred from the data is surprisingly small. According to equation (2), it formally implies a helium abundance $\xi = n(\text{He})/n(\text{H}) = (0.3^{+1.3}_{-0.7})$ per cent. This is only a small fraction of the value observed in emission nebulae[7], and in *O* and *B* stars[8] and is not acceptable. One may question the validity of the adopted cross-section for helium in equation (2). It agrees, however, within 10 per cent with an experimental determination at 0.28 keV (ref. 9) and correlates well with other data at lower energies[10]. Furthermore, if additional interstellar hydrogen were present in a form other than atomic (such as H_2 or H^+) the discrepancy would be still worse.

It is interesting that ultraviolet observations of stars also indicate a discrepancy with the 21 cm column densities[11]. Lyman-α measurements indicate that N_H (21 cm) may be as much as a factor 6.5 too high. Our measurements indicate that N_H (21 cm) may be a factor 3.3 too high if ξ is 0.10. If this discrepancy is real, it has profound implications for the interstellar medium.

We find that j_0 may be reasonably interpreted as a continuation of the background spectrum already observed above 1 keV. For example, a power law with $\alpha = 1.8$ fits the points from 0.28 to 30 keV quite well (confirming our use of $\alpha = 1.6$ in the data reduction). Such a spectrum is consistent with either emission by distant discrete sources or inverse Compton scattering of 3° black-body background quanta in intergalactic space. In this case, the observed steepening of the spectral index by about 0.5 somewhere between 10 and 100 keV may have great significance.

The present measurement may be employed to place limits on the temperature of a dense intergalactic medium. It was shown by Field and Henry[12] that an upper limit on the temperature of a postulated intergalactic gas can be obtained from the observations of the diffuse background in the 2–10 Å region. If the gas is assumed to be heated at the epoch $z = 1$, and if its density is sufficient to give $q_0 = 1$, the present gas temperature must be less than 2×10^6 °K. Weymann[13] has computed more realistic models, based on definite heating mechanisms and including free-bound emission and emission by helium in addition to free–free emission by hydrogen. His upper limit from the 2 to 10 Å data is also about 2×10^6 °K because the latter dominates at high temperatures.

The present data at lower photon energies are sensitive to lower temperatures. From Weymann, we find $T < 3 \times 10^5$ °K if the predicted thermal emission is not to exceed the observed flux. Even if helium and free-bound emission are omitted[12], $T < 5 \times 10^5$ °K.

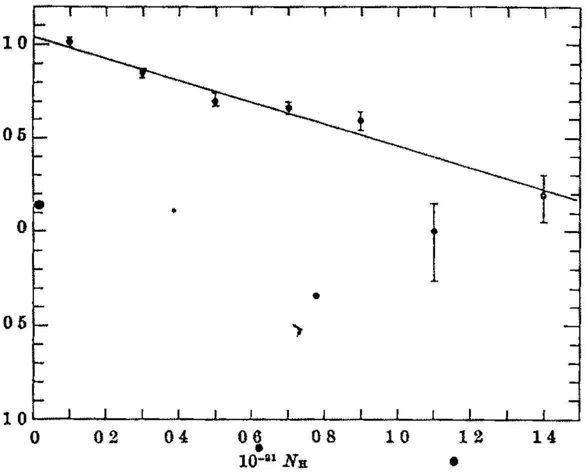

Fig. 3. Correlation between observed count rate and calculated interstellar absorption. The abscissa is the column density of interstellar atomic hydrogen, which is proportional to the expected absorption, and the ordinate is count rate (0.5 sec intervals). The correlation represented by the line confirms the hypothesis of extragalactic origin. The intercept yields the count rate corrected for absorption, and the slope yields the cross-section per hydrogen atom.

If quasars are at cosmological distances, Weymann has shown that $T > 1 \times 10^6$ °K from the absence of intergalactic Lyman-α absorption. We may set a lower limit on T from the present data alone, which is independent of the controversial issue of quasar distances, although it does depend on the assumption that the abundance of primordial helium is about 10 per cent. If T were lower than 10^5 °K, thermal emission at 44 Å would be negligible, requiring that the observed flux be attributed entirely to nonthermal sources. If, as seems very likely, these sources are at a great distance, they will be attenuated by the intergalactic gas[4,14] if any atoms are present which are not completely ionized. For $q_0 = 1$ and 10 per cent helium abundance, this requires that less than a few per cent of the helium can be neutral or singly ionized. From ref. 13, this in turn requires that $T > 10^5$ °K.

We may therefore conclude that the present temperature of a postulated dense intergalactic gas must lie in the narrow range $1 \times 10^5 < T < 3 \times 10^5$ °K. Such values agree very well with a theoretical prediction by Sciama[15]. It is important to note, however, that a valid alternative explanation is simply that the intergalactic gas is not dense and that it contributes a negligible amount to the mass of the Universe. If future experiments eliminate the permitted range of temperature altogether, we shall be forced to the latter conclusion.

Finally, we consider the interpretation of the anomalous emission component. If it is indeed a real effect, its direction is not far from the direction of the galactic nucleus. Its intensity decreases at low galactic latitude as would be expected for a distant source. We have considered the possibility that this source is caused by a galactic corona of the type proposed by Spitzer[16]. We estimate that its maximum intensity at 0.28 keV, corrected for interstellar attenuation, is about 1.8×10^{-24} erg cm^{-2} sec^{-1} ster^{-1} Hz^{-1}. If we include a small contribution by helium and by bound-free emission, the thermal radiation from the hot gas would equal the value suggested by the observations if $T = 10^6$ °K and the emission measure $\int N_e^2 \, dl = 0.7$. Such a corona would not be observable optically or at radio wavelengths. If we suppose it to be a spherical cloud centred on the galactic nucleus, its radius would be about 5 kparsec and N_e would be about 10^{-2} cm^{-3}. The gas pressure would be about 2×10^{-12} dynes cm^{-2}, about twenty times the value suggested by Spitzer. Its mass would be $10^8 M_\odot$. If the anomalous emission is caused by another effect, these figures represent an upper limit on a possible galactic corona.

We thank Dr Burton Henke for assistance in the calibration of the detector window and Dr Dennis Sciama for a number of useful discussions. This work was supported by a NASA contract to the Catholic University of America and by a NASA grant to the University of California at Berkeley.

Conformational Relationship between the O–C–C–N+ System of Phospholipids and Substrates of Muscarinic and Cholinergic Systems

by

M. SUNDARALINGAM

Department of Chemistry,
Case Western Reserve University,
Cleveland, Ohio

The O–C–C–N+ system is a common structural feature of phospholipids and nerve amines and it displays the *gauche* conformation about the carbon–carbon bond. The characteristic *gauche* conformation is probably associated with the biological activity of the phospholipids and the nerve amines. The close structural relationship between the phospholipid components and acetylcholine suggests that the lecithins and the sphingomyelins of cell membranes may be competitive inhibitors and sites of concentration of acetylcholinesterase

In a recent communication on the crystal structure of the phospholipid component L-α-glycerophosphorylcholine cadmium chloride trihydrate[1], it was pointed out that the choline residue displayed a *gauche* conformation about the C–C bond (Fig 1) Choline and ethanolamine derivatives are widely distributed as components of membrane phospholipids and nerve amines Examination of several of these compounds, the solid state structures of which are known, revealed that the O–C–C–N+ system always exists in the *gauche* form (my unpublished results, see also ref 2), rather than the *trans* form which would be expected on purely steric grounds I contended that electrostatic attraction between the positively charged nitrogen and the electronegative oxygen (ester, ether or alcohol oxygen) stabilizes the *gauche* conformation

There can be two enantiomeric *gauche* conformations, I and II, in I the OCCN+ angle is positive while in the other this angle is negative Crystal structures, which have a mirror plane (glide plane) of symmetry or a centre of symmetry, would display both these forms The torsion angles φ_{CC} (for definition of φ_{CC} (ref 3) see Fig 2), for the compounds under consideration, are listed in Table 1 Irrespective of whether the compound is a zwitterion or one that possesses only a positively charged nitrogen, it is observed that the conformation about the C–C bond is *gauche* The intramolecular N+ O distances shown in the figures may be regarded as being close to or slightly less than the van der Waals contacts, indicating that there is substantial electrostatic interaction between the quaternary nitrogen, N+, and the electronegative oxygen, thus supporting the contention that N+ O coulombic attraction is primarily responsible for the folded conformation

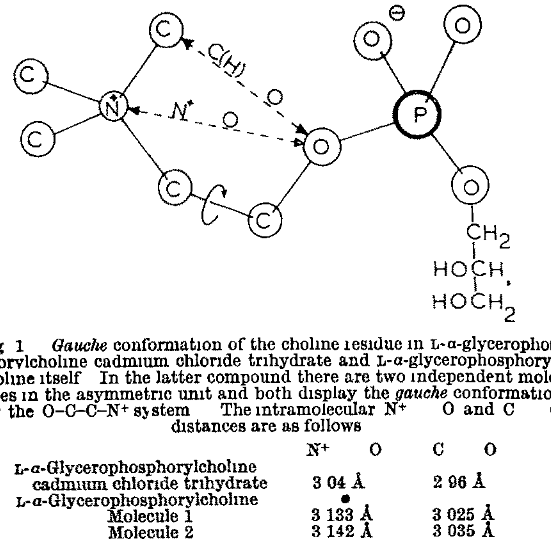

Fig 1 *Gauche* conformation of the choline residue in L-α-glycerophosphorylcholine cadmium chloride trihydrate and L-α-glycerophosphorylcholine itself In the latter compound there are two independent molecules in the asymmetric unit and both display the *gauche* conformation for the O–C–C–N+ system The intramolecular N+ O and C O distances are as follows

	N+ O	C O
L-α-Glycerophosphorylcholine cadmium chloride trihydrate	3 04 Å	2 96 Å
L-α-Glycerophosphorylcholine		
Molecule 1	3 133 Å	3 025 Å
Molecule 2	3 142 Å	3 035 Å

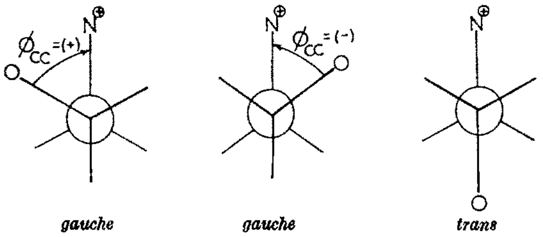

Fig 2 The three possible staggered arrangements for the O–C–C–N+ system as viewed down the C–C bond The torsion angle φ_{CC} (ref 3) is said to describe a *gauche* conformation when the projected angle between the C–O and C–N+ bonds is ±60°, the positive angle is measured clockwise from the C–O bond to the C–N+ bond

Furthermore, the positive charge on the nitrogen would be expected to be at least partially delocalized into the methyl groups Possible C–H O hydrogen bonds[3] involving the C–H bond of the methyl group closest to the oxygen atom can therefore provide additional stabilization of the *gauche* conformation in the choline derivatives where the H–C N–C–C–O chain achieves a quasi six-membered ring, as shown in Fig 3 Even in the zwitterions it seems that the *gauche* conformation is stabilized by the interactions discussed (N+ . . . O) rather than the electrostatic interaction between the positively charged nitrogen and the anionic oxygen.

The cadmium chloride complex of L-α-glycerophosphorylcholine exhibits a torsion angle of about +60° In L-α-glycerophosphorylcholine itself[4], however, while the two independent molecules comprising the asymmetric unit of the crystal structure are *gauche*, their torsion

* After this article was submitted for publication, Carlstrom and Bergin (*Acta Cryst*, **23**, 313, 1967) reported the crystal structure of the brain amine noradrenaline hydrochloride, in which the O–C–C–N+ system also occurs in the *gauche* conformation with φ_{CC} about −60°

angles have opposite signs, namely +71·5° and −75·3° (Table 1) The remaining choline derivatives in the table with the O–C–C–N$^+$ system are not zwitterions and, interestingly, are related to the substrates of muscarinic and cholinergic systems, for example, muscarine iodide[5], choline chloride[6], acetylcholine bromide[7,8], and palmityl- and stearylcholine bromides[9,10] These compounds exist in the *gauche* conformation in their respective crystals (Fig. 4)

The two ethanolamine derivatives—ethanolamine phosphate and L-serine phosphate—are components of the important phospholipids (cephalins), phosphatidylethanolamine and phosphatidylserine, respectively Again, both these components demonstrate the *gauche* form in the solid state, although here the substituents on the N$^+$ are hydrogen and not methyl groups The N$^+$ . . O distance in ethanolamine phosphate[11] is 2·878 Å, which not only is appreciably shorter than the corresponding values found in the choline derivatives, but is also significantly shorter than the van der Waals contact distance (Fig 5) The absence of methyl groups on the nitrogen in the ethanolamine derivatives therefore makes possible a closer approach of the quaternary nitrogen and the phosphate ester oxygen, and the N$^+$ . . O coulombic attraction is probably the only dominant force that twists the molecule into the *gauche* form Hydrogen bonding interactions involving the hydrogens on N$^+$ and the ester oxygen are of little importance here because not only are the H . . O distances greater than 2·90 Å but also the N–H . . O angles, close to 90° or less, are unfavourable for an N–H . . O hydrogen bond The N$^+$ . . O distance in L-serine phosphate[12] is not available because the atomic co-ordinates were not reported, however, the *gauche* arrangement in L-serine phosphate was deduced from the published perspective drawing (redrawn, Fig 6)

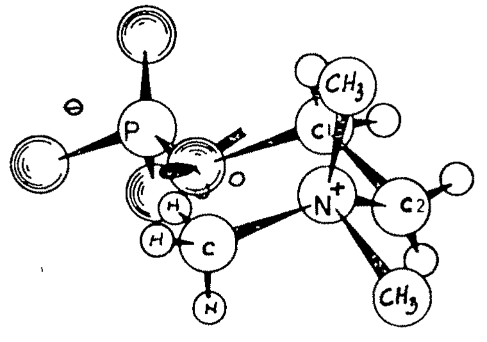

Fig 3 C–H . . O interaction between a methyl C–H bond and the ester oxygen atom in the glycerophosphorylcholines is achieved by the quasi six-membered ring formed by the O–C–C–N$^+$–C–H chain

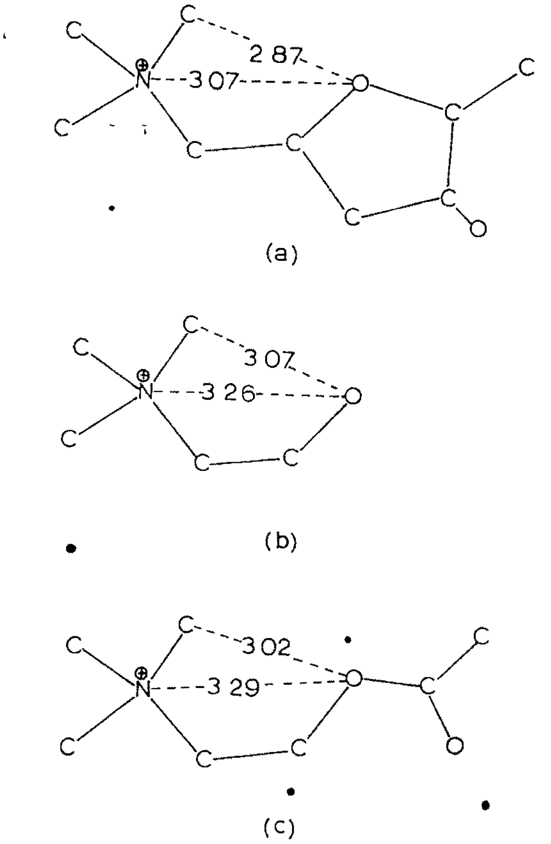

Fig 4 The *gauche* conformation of the O–C–C–N$^+$ system in muscarine and choline derivatives (*a*) muscarine iodide, (*b*) choline chloride and (*c*) acetylcholine bromide In all three compounds the organic residue is a cation rather than a zwitterion as found in the phospholipid components, ethanolamine phosphate, L-serine phosphate and L-α-glycerophosphorylcholine

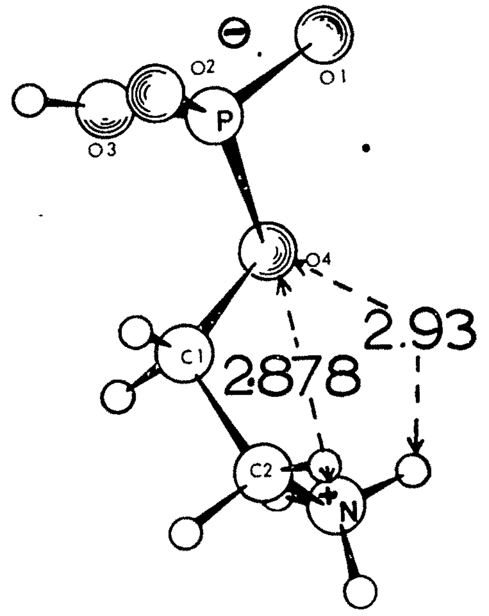

Fig 5 The *gauche* conformation in ethanolamine phosphate

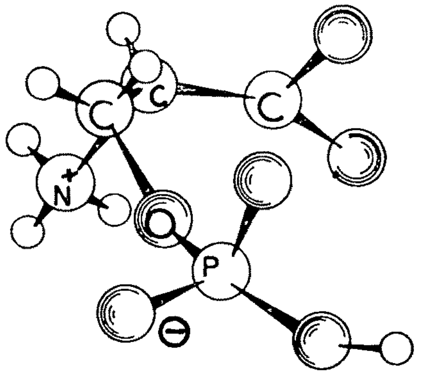

Fig 6 The *gauche* conformation in L-serine phosphate.

DL-Serine[13] also exists in the *gauche* form (Fig 7) Apparently the presence of the alpha carboxyl group in L-serine phosphate and DL-serine does not affect the preferred *gauche* conformation of the O–C–C–N$^+$ system Serine and threonine are the only amino-acids which possess the O–C–C–N$^+$ system While phosphatidylserine occurs abundantly in cell membranes, phosphatidylthreonine is not widespread in biological membranes, a surprising fact in view of the *gauche* arrangement of the O–C–C–N$^+$ system in the crystal structure of L$_S$-threonine[14] While φ_{CC} is negative (about −60°) in L-threonine, it is positive in L-serine phosphate The lack of occurrence of phosphatidylthreonine in cell membranes may be attributable to the presence of the beta methyl substituent in threonine, which might interfere with the conformation of the phospholipid, the packing of the phospholipid in the membrane, and the formation of the phospholipid–cholesterol complex in the membrane.

Although detailed structural information on the phospholipids is not yet available, it is very likely that their choline and ethanolamine components prefer the *gauche* conformation, at least in the solid state. Recently, Culvenor and Ham[15] have also found the *gauche* conformation for acetylcholine from studies of the proton magnetic resonance spectra of aqueous solutions of acetylcholine bromide. In the solid state this compound displays the enantiomeric *gauche* forms[8] by virtue of the presence of the glide plane of symmetry in the crystal.

Acetylcholine, a nerve transmitter, when released at nerve endings is rapidly hydrolysed by the readily available enzyme acetylcholinesterase, which is found associated with the cell membranes. The presence of the choline residue in the lecithins and sphingomyelins of membranes has prompted me to speculate that these membrane phospholipids may function as competitive inhibitors of the enzyme acetylcholinesterase (phosphorylcholine itself is a strong inhibitor of acetylcholinesterase[16]) and may play a part in the storage of this enzyme in cell walls, in which the cationic groups ($(CH_3)_3N^+-$) of the phospholipids may serve as binding sites[17] for acetylcholinesterase.

The release of acetylcholine in nerve endings is accompanied by an increase in the ion permeability of excitable membranes. This increase in ion permeation is probably correlated with the acetylcholinesterases detaching themselves from the cationic sites of the membrane phospholipids in order that they can now employ their cationic sites to carry out the hydrolysis of acetylcholine. The charged groups of the "freed" ($(CH_3)_3N^+-$ group of phospholipids not bound to cholinesterase) phospholipids are then available to take part in the transport of ions through the cell wall. In addition, the free phospholipids may undergo conformational changes in the vicinity of the charged groups that could also promote ion transport. When the acetylcholinesterase has completed the hydrolysis of acetylcholine, however, salt secretion is once again arrested. This may be interpreted as being caused by the "deactivation" of the phospholipids ($(CH_3)_3N^+-$ group of phospholipids bound to cholinesterase) by the re-formation of the cholinesterase–phospholipid complex. It must be remembered that the above is only one of the numerous processes that probably occurs during ion transport.

Apparently, the N^+–C–C–O system is one of the requirements for the membrane phospholipids. It will be of interest to investigate the effect of $N^+(C)_nO$ chain length on these phospholipids. It has not yet been established whether the *gauche* conformation (about $+60°$ or about $-60°$) of N^+–C–C–O is necessary for biological activity of the phospholipids. It is possible, however, that there is a critical distance between the positively charged nitrogen (cationic site) and the anionic phosphate oxygens (esteratic site) for phospholipid activity (see also refs. 18 and 19). If the N^+–C–C–O chain of the lecithins and cephalins occurs in the *gauche* form, this critical distance probably is achieved, and therefore permits the formation of the enzyme–substrate complex.

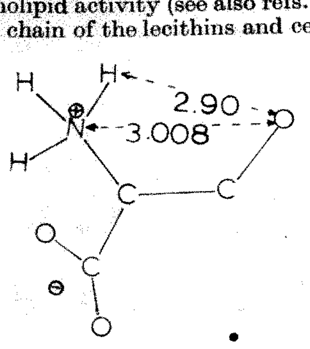

Fig. 7. The *gauche* conformation in DL-serine.

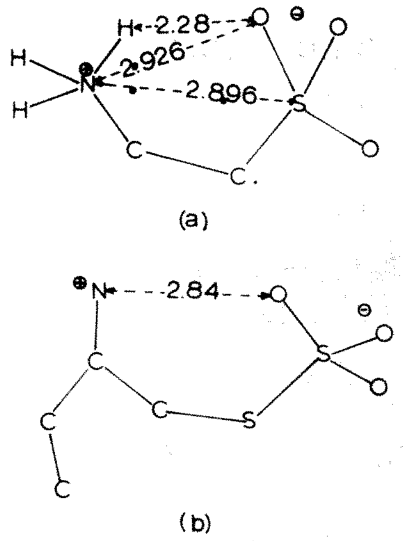

Fig. 8. The *gauche* conformation of the N^+–C–C–S system is stabilized by intramolecular N–H . . . O hydrogen bond in (*a*) 2-aminoethylsulphonic acid, and (*b*) *d,l*-2-aminobutylthiosulphuric acid.

The S–C–C–N^+ system in acetylthiocholine (private communication from E. Shefter and H. G. Mautner) and the Se–C–C–N^+ system in acetylselenocholine[2] display the *trans* conformation about the C–C bond. Increase in the nonbonded interactions, S . . . N^+ and Se . . . N^+, arising from the larger substituents (sulphur, selenium) and a decrease in the coulombic attractions (because sulphur and selenium are less electronegative than oxygen) are possibly responsible for the preferred *trans* conformation in these compounds.

It should be noted that the *gauche* conformation of the S–C–C–N^+ system in 2-aminoethylsulphonic acid[20] and 2-aminobutylthiosulphuric acid[21] (Fig. 8) is stabilized for a different reason, namely the presence of an intramolecular N^+-H . . . O^- hydrogen bond between the quaternary nitrogen and the anionic oxygen of the sulphonic acid and the thiosulphuric acid, thus forming a quasi six-membered ring zwitterion in the first and a quasi seven-membered ring zwitterion in the second.

In rats with congenital rubella, following maternal infection during pregnancy, the pathogenic effects and persistence of the virus after birth are remarkably similar to conditions prevailing in human infants with congenital rubella.

ALTHOUGH the rubella virus has been cultured *in vitro* and the methods for its propagation, identification and quantitation are available, the teratogenic effects of the virus and cellular pathological effects in various animal species *in vivo* have not been well established. Several attempts have been made to induce congenital rubella disease in animals. Sever and co-workers infected pregnant rhesus monkeys with rubella virus but found no evidence of malformation or infection in the foetuses which were delivered by caesarean section[1]. Experiments of Parkman *et al.* indicated a transplacental passage of the virus in monkeys and the possibilities of inducing a congenital rubella syndrome in animals[2]. There are, however, practical reasons for avoiding the monkey as an experimental animal. These are principally the problems of breeding and mating primates, the need for accurate determinations of the beginning of pregnancy, the length of the pregnancy (6 months) and the final surgical delivery of the babies. Rabbits, hamsters and ferrets have been injected with rubella virus during pregnancy and there was a decrease in the size and growth of the offspring[3]. In the series of experiments reported here, we found that the rat presents definite advantages for studies of experimental congenital rubella.

Pregnant albino rats, weighing 200–250 g, were obtained from the Hormone Assay Laboratories (Chicago, Illinois) and housed in individual cages. The day of pregnancy had already been established by vaginal smear at the supplying laboratories and found to be correct in more than 95 per cent of animals. The rats had a 3 week pregnancy period and the ova became implanted 4 days after fertilization. Approximately two hundred mother rats were used (thirty–forty rats in each experiment). The animals were injected intramuscularly in the hind legs with 0·25–0·60 ml. of a rubella virus suspension containing 10^3 $TCID_{50}$ (tissue culture infective dose) of the Bodak strain which was initially obtained from the Fifth Army Infectious Diseases Laboratories (St. Louis, Missouri), and propagated in $LLCMK_2$ cells (African green monkey kidney cells from Eli Lilly Company, Indianapolis, Indiana) which were cultured in roller tubes. Viral titrations and identifications were established before injection by the indirect interference techniques with Echo II virus developed by Parkman *et al.*[4]. Control rats had either been injected with heat inactivated virus or else had not been injected.

Rubella virus was identified in the tissues of embryos and newborn rats by the immunofluorescent technique of Woods *et al.*[5]. The embryos were obtained from 15 day pregnant mothers which had been injected on the fifth or sixth day of pregnancy as described. The embryos were frozen in liquid 'Freon' at −150° C, and serial frozen sections were processed. Alternate sections were exposed to human serum containing rubella antibodies (titre 1 : 32). All sections were incubated at 38° C with a 1 : 8 dilution of fluorescein-labelled purified goat antiserum to human gamma globulin. The tissue sections, as well as simultaneously processed tissue cultures which had been grown on cover slips and which had either been infected with rubella, or else were uninfected, were then examined with the ultraviolet Leitz microscope, and photographed on high speed 'Ektachrome *ASA* 160'. Viral antigens, when present in rubella infected cells, showed up as intense perinuclear and diffuse cytoplasmic fluorescence.

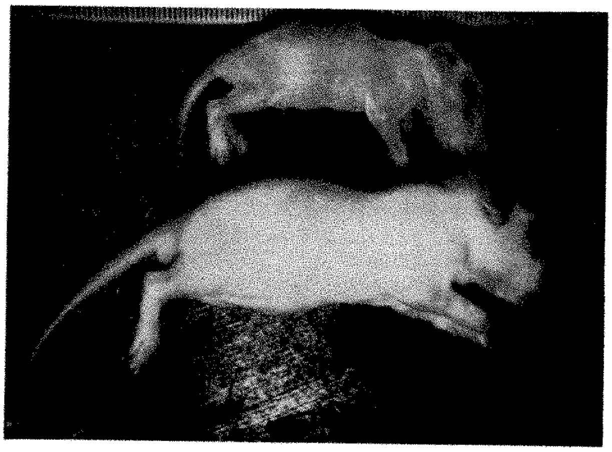

Fig. 1. 15 day old congenital rubella rat (top) and control rat of same age (bottom).

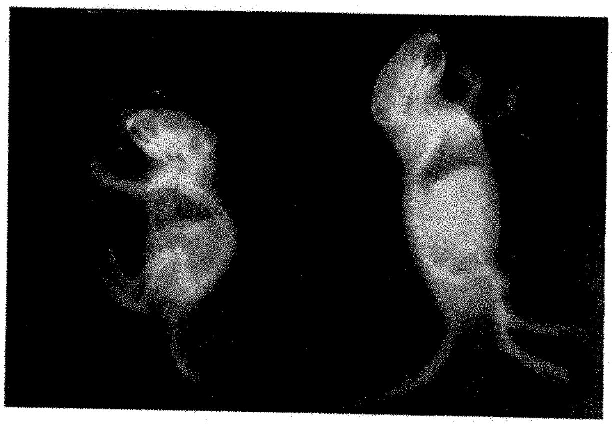

Fig. 2. Skeletal radiograph of rats in Fig. 1. Left: congenital rubella rat. Right: control rat.

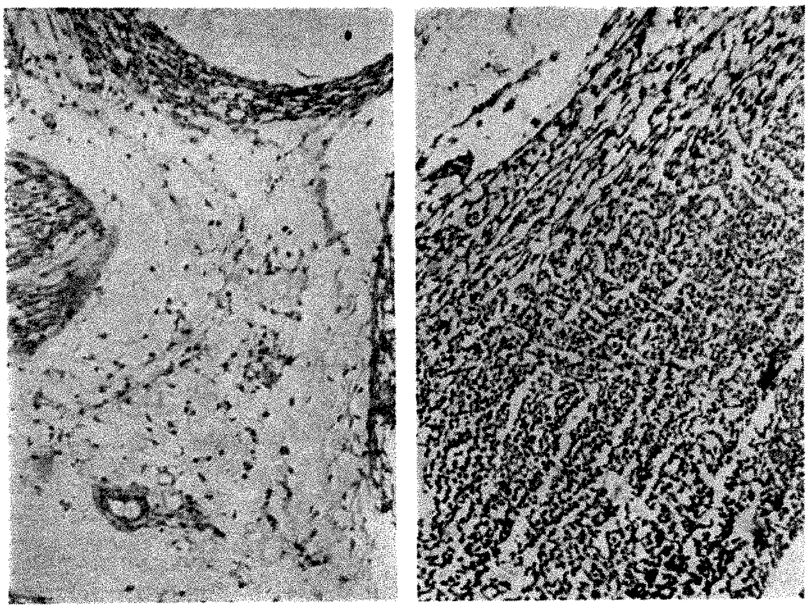

Fig. 3. Myocardial ventricular septum of (*A*) newborn congenital rubella rat and (*B*) newborn control rat (haematoxylin and eosin, × 200).

Controls and rats which had been injected with rubella were allowed to deliver. A most evident finding was the high incidence of neonatal deaths in the offspring of rats which had been injected with rubella, as compared with control rats. The results of four successive series of experiments are shown in Table 1. The intramuscular injection of rubella virus of the Bodak strain during the fifth and sixth day of rat pregnancy resulted in a high incidence of death of the offspring during the first month and a half after birth. Daily examination and measurements of the animals showed a marked decrease in the size and weight of the rubella offspring (weight 20–40 per cent of that of controls) (Fig. 1), and the X-rays showed alterations which were typical of retarded bone growth (Fig. 2). The rubella offspring were cyanotic (bluish abdominal skin) and extremely cachectic in the days preceding death. Rats with congenital rubella had purpura (10 per cent), opacities in the lenses (25 per cent) and obvious malformations such as open fontanelles (2 per cent) and missing hind legs (1 per cent). After either intramuscular injection or intramuscular and oral spraying, the mother rats did not show signs of rubella rash or lymphadenopathy and moved about the cages in the same way as their corresponding controls.

The rats with congenital rubella showed pathological changes in the intraventricular septum of the hearts and in the crystalline lenses and retinae of the eyes: intraventricular septa were markedly thin and atrophic (Fig. 3*A* and *B*), and infected crystalline lenses showed destruction of the lens fibres and epithelial cells, necrotic areas in the centre of the lens and vacuolation of the cortical areas. The pathological condition of the lens was similar to that described in the lenses of human rubella syndromes by Boniuk and Zimmerman[6]. As seen by electron microscopy, some lens cells had lost all electron opaque DNA and contained a nucleus partially filled with debris, while others had marked "clumping" of DNA material (Figs. 5 and 6). Although the magnification which was obtained did not allow definite statements, isolated, round viral-like particles of approximately 500 Å in diameter could be identified among nuclear debris. Immunofluorescent techniques showed that rubella virus was present in crystalline lens, heart and retina of embryos in newborn rats (Fig. 4). Other tissues from newborn animals were negative.

Table 1. MATERNAL INFECTIONS WITH RUBELLA VIRUS (BODAK STRAIN) AND RATE OF NEONATAL DEATH

Pregnancy day	Dose		Newborns surviving at the indicated days after delivery: 3 days	45 days	Percentage death
		Controls:	80	**72**	**10**
5	0·1 ml. IM		46	23	50
	0·2 ml. IM		93	54	42
	0·4 ml. IM		20	5	75
		Total	159	82	48·5
6	0·1 ml. IM		51	49	4
	0·2 ml. IM		68	40	41
	0·3 ml. IM		38	22	42
		Total	157	111	29
8	0·2 ml. IM + 0·2 ml. oral		15	15	0
9	0·2 ml. + 0·2 ml. oral		23	19	18
11	0·2 ml. IM + 0·2 ml. oral		25	25	0

IM, Intramuscular injection.

The surviving litters of rats with congenital rubella were of smaller size and weight. The histology of the kidneys, livers, brains, lungs, bones and eyes of these animals was normal. No additional deaths were recorded among the litters 45 days after birth.

Oxford has described the growth of rubella virus in small laboratory animals, and suggested that it might be

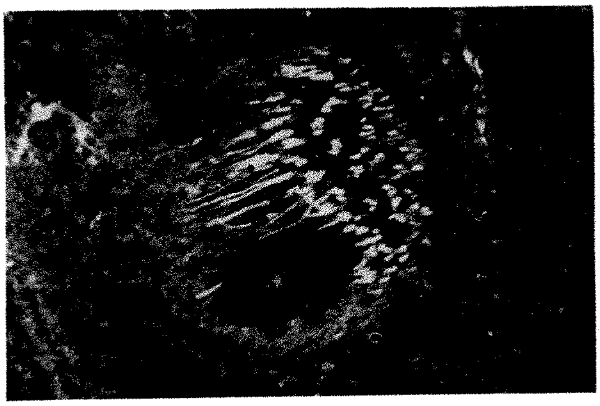

Fig. 4. Section through lens and optic vesicle of 15 day old rat embryo infected with rubella virus at day 6 of gestation. Fluorescence of rubella virus in nuclei and elongating epithelial cells of the lens vesicle (× 200).

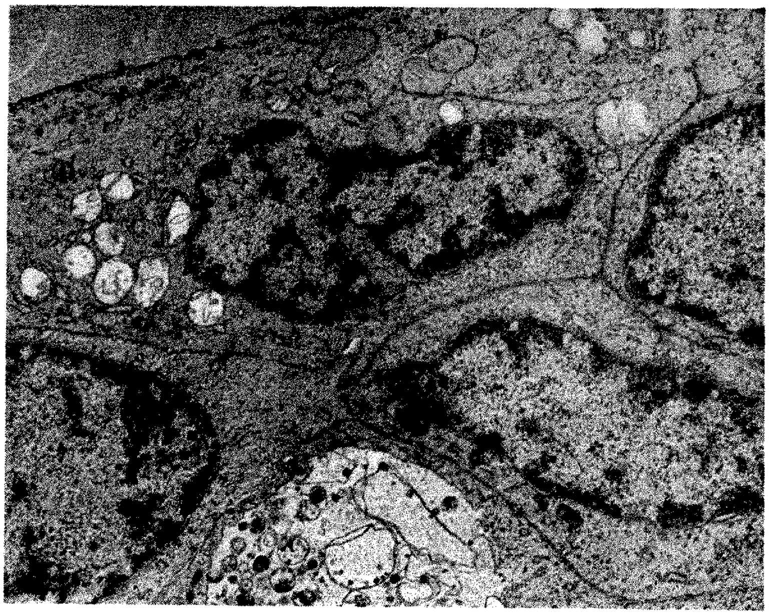

Fig. 5. Lens epithelium of 14 day old rubella rat. In the upper left area: the intact lens capsule. Below and centre: a cell showing destroyed nuclear DNA. Other epithelial cells are not infected (× 15,000).

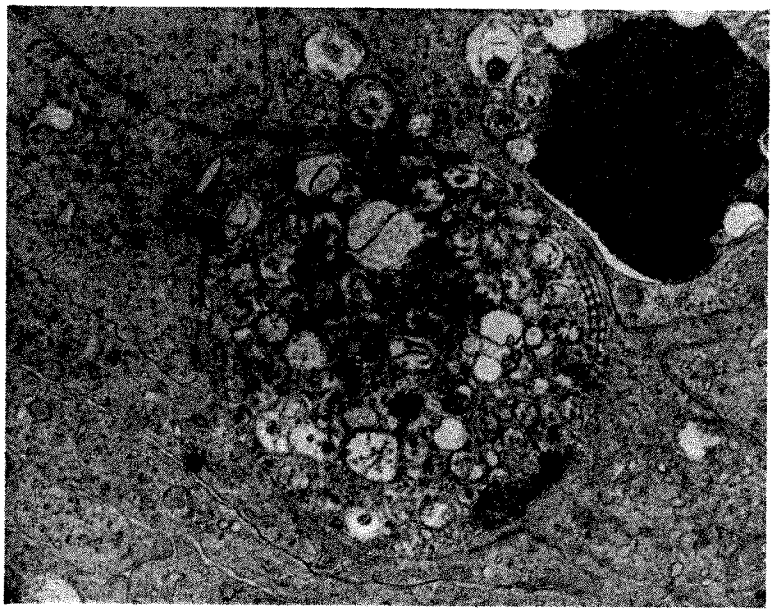

Fig. 6. Destruction and "clumping" of DNA in the nuclei of two equatorial lens fibres (× *c*. 18,670).

used for studies of the teratogenic effects of the virus[7]. In rats with congenital rubella the pathogenic effects and persistence of virus after birth are remarkably similar to those described in human infants with congenital rubella. The prominent clinical signs in the human disease are the intraventricular septal defect, cataracts, retinopathy and deafness[8]. Of interest is the specific pathogenic effect of the rubella virus on the nuclear DNA of isolated lens epithelium cells. It would seem that the virus infection and destruction of the genetic apparatus of these cells are in some way related to the decreased rate of replication of cells and size of organs infected by the virus. Plotkin and Vaheri have reported on the inhibition by rubella virus of growth and cell count of normal human diploid cells which were cultured *in vitro*. In their studies, the antimitotic activities on rubella virus infected cells were exerted on DNA synthesis as shown by a cumulative reduction of cells taking up tritiated thymidine[9].

LETTERS TO THE EDITOR

ASTRONOMY

Radio Sources in Opposite Directions as a Cosmological Test

FROM the observed distribution of quasi-stellar sources versus red-shift an excess of sources with red-shifts between 1·9 and 2·1 is noticed. Petrosian *et al.*[1] showed that this effect may be explained in a cosmological model where the pole is in this red-shift range.

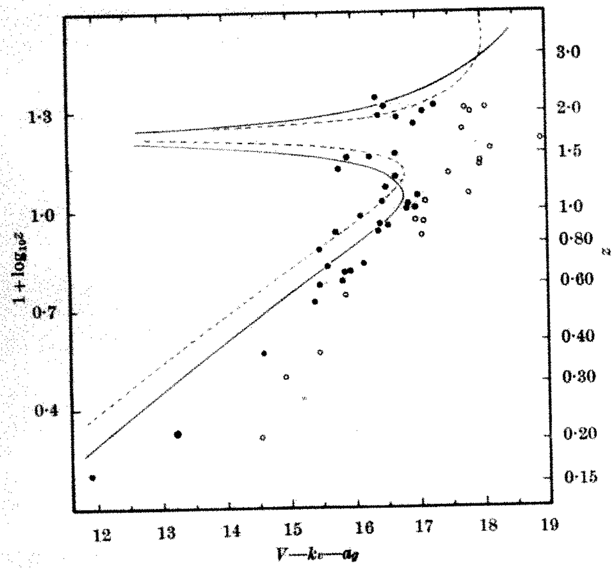

Fig. 1. Magnitude–red-shift relations for brighter quasars. The magnitudes are corrected for K-correction[3], k_v, and galactic absorption (unpublished work of G. de Vaucouleurs and G. Malik), a_g, assuming 0·25 mag. absorption at the galactic pole. The black dots represent the brightest quasars which may represent a class of objects with a standard absolute magnitude. The selection is arbitrary; a few of the fainter quasars are shown as open circles. The two models shown are based on a Hubble parameter $H_0 = 100$ km sec^{-1} Mparsec^{-1}, q_0 is the deceleration parameter and σ_0 a density parameter, $\sigma_0 = 4\pi G\varrho/3H_0^2$ where ϱ_0 is the mean density of the universe. Models: ——, $q_0 = -1·5$, $\sigma_0 = 0·132$, $M_v = -27·3$; – – – –, $q_0 = -1·4$, $\sigma_0 = 0·085$, $M_V = -27·8$.

In Fig. 1 the red-shifts and magnitudes are shown for the brighter quasars. The data are from a list compiled by Barbieri *et al.*[2] and the magnitudes plotted are corrected for K-correction[3] and for absorption in our own galaxy (unpublished work of G. de Vaucouleurs and G. Malik). Two theoretical models with a pole for z about 1·7 are shown which are in good agreement with the observations.

Models where the pole has a red-shift of the order 2–3 or less suggest an interesting cosmological test—that is, the possibility of observing the same object in two opposite directions in the sky. The question discussed here is the possibility that sources in the 4*C* radio catalogue[4] may show this effect.

The 4*C* radio catalogue contains one part between declination −7° and +7° where it is possible to compare positions 180° apart in the sky. In the following the notation R is used for a test of sources 180° apart and C_1 and C_2 for two control tests (areas opposite in declination or opposite in right ascension only).

In the catalogue, we have mean errors in position up to 12′ in declination for the fainter sources. This may give mean separations up to 14′ on sources which are exactly opposite. If we have a cosmological model as shown in Fig. 1, we may see two images of the same object at different epochs. The time difference may be of the order 10^9 years. If the object has a proper motion of 50–100 km/sec, which is found for ordinary galaxies[5], this will easily make a separation of the two images of the order 10′ because of the enlargement of apparent size close to the pole. If double image objects could be observed, we should then expect them to show a characteristic separation of at least 10′ from exact opposite positions.

In the project described here, pairs with separations up to 75′ have been investigated. The results are shown in Fig. 2 for R and the two control areas C_1 and C_2. The quantity plotted is the number density of sources in different rings of separations or N/a, where N is the number of sources and a is the separation. The pair count is performed for all sources in the strip of the catalogue and also for faint and bright sources separately. Pairs for which the total flux is less than 6·35 flux units are considered as faint. This represents about half the pairs.

In Fig. 1 the expected pair densities are shown as broken lines. The slopes of these lines are explained by

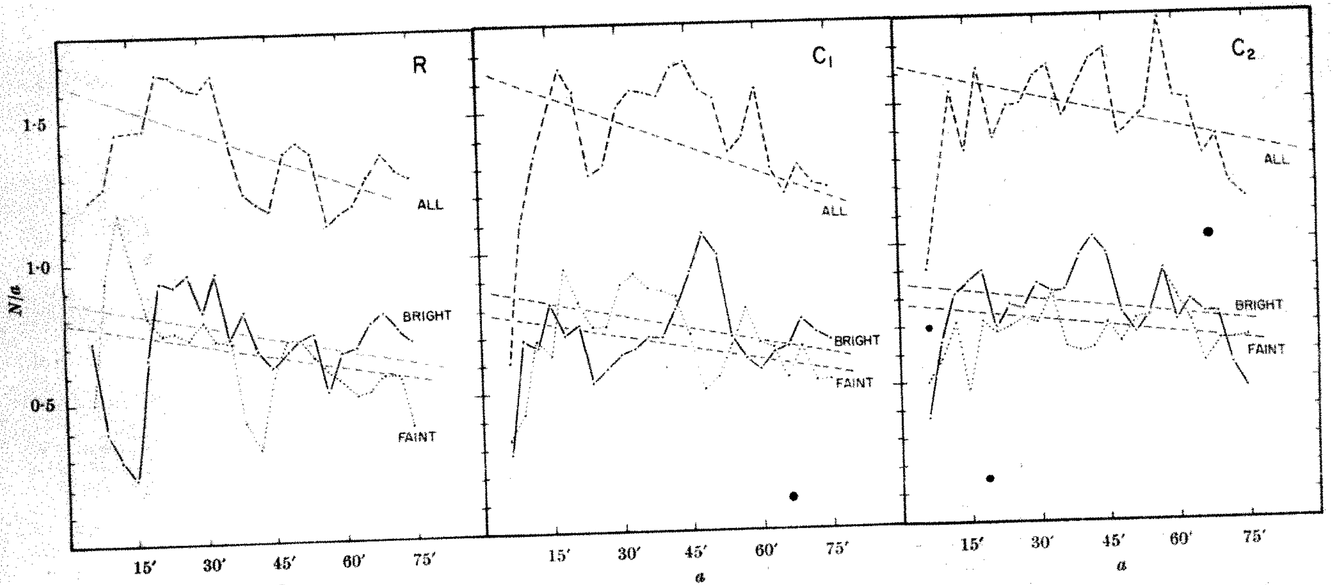

Fig. 2. The surface density (N/a) for the three different test areas shown as a function of the separation a. The distributions of the brighter and fainter pairs are also shown. The broken lines indicate the expected distribution. The separation $a = 3′$ is used as a unit.

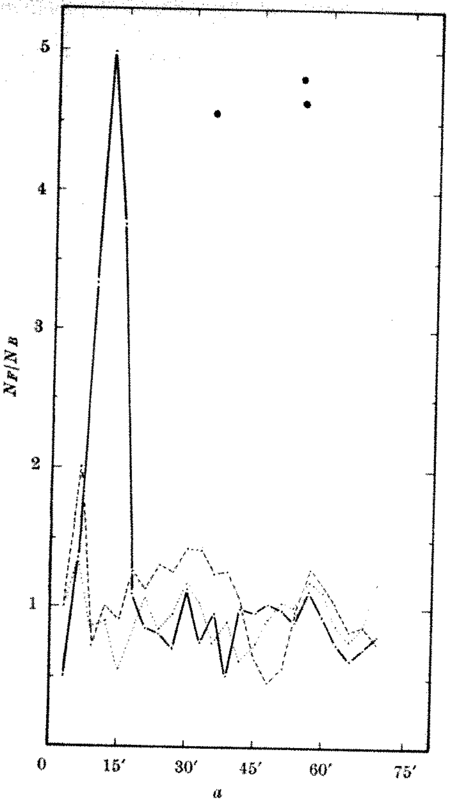

Fig. 3. The ratio of faint to bright pairs in the three different test areas. ----, C_1; ····, C_2; ——, R.

the loss of possible pairs at the boundaries of the areas investigated. Areas of confusion, as listed in the catalogue, are excluded as are sources less than ± 10° from the galactic plane. The figure shows that the distribution of all the pairs together is what might be expected from a random distribution. When we study the distribution of the faint and the bright pairs separately, we note a difference in R for separations less than 15′. We find an excess of faint close pairs and a deficiency of bright close pairs in R. The deficiency of bright sources in R is somewhat more pronounced than in C_1 and C_2, but may not have any special significance. The excess of faint sources in R may be significant, if real.

The difference between the tests R and C_1 or C_2 is evident in Fig. 3, which shows the proportion of faint to bright pairs at different separations. The effect demonstrated is the combined result, in the area R, of the excess of faint sources and the deficiency of bright sources with small separations. The excess of faint sources in R is concentrated in the range $10' < a < 16'$. Comparing the counts with the expected number of pairs in this range for a random distribution, we find an excess of 5·8 ± 2·3 faint pairs. The probability of this excess happening by chance is 0·012. If we instead compare the count in R with the actual observed distribution of faint pairs in C_1 and C_2, we find an excess of 6·5 ± 2·3 faint pairs. The probability of this departure is 0·006. We conclude that, at the 98–99 per cent confidence level, there is evidence for an excess of faint sources in almost exactly opposite positions as given in the 4*C* radio catalogue.

If this effect is real, possible explanations may perhaps be found in some properties of the distribution of faint radio sources such as clustering effects, or perhaps in unrecognized systematic errors of position determinations in the catalogue. I prefer, however, to suggest that the effect is the result of the well known cosmological property that in some closed universe models it should be possible to see the same object in two opposite directions.

In closed universe models, in which the pole is within the particle horizon[6], information can be received from objects beyond the pole; such objects should be observable in two nearly opposite directions with suitable instruments. For this purpose we require objects such as radio galaxies or quasars with a lifetime of the order of the difference in travel time between the two opposite light paths (about 10^9 years). Disturbances of the light rays caused by passage through clusters of galaxies may introduce a small displacement of the two images with respect to each other and may also cause blurring[1] in addition to the displacement from proper motion described here.

The observed excess of faint pairs is in the range of separations from 10′ to 15′, the mean separation being 13′·2 ± 2′·9. The chief component of this separation may be the result of errors in determining positions, but may also contain a component indicating a real position difference of the order 5′ to 10′ linked with the effects mentioned here.

In uniform relativistic world models, the observation of the same object in opposite or nearly opposite positions would indicate rather specific values of the cosmological parameters q_0 and σ_0 (ref. 7, Fig. 8). The red-shift of the pole cannot be much greater than 2 if we are to observe this effect, which restricts the value of q_0 to close to −1·5 and σ_0 of the order 0·1 if we also have the magnitude–red-shift distribution of quasars in mind (Fig. 1). This is not in contradiction with the values obtained by testing red-shift–magnitude relations for galaxies in clusters when evolutionary effects are taken into account[9].

As a check on the reality of the interpretation presented here, we expect that in the 4*C* data a characteristic separation would show up more clearly in right ascension than in declination because the positions are more accurate in right ascension. Fig. 4*a* shows the distribution in total separation of the closest nineteen pairs at the fainter part of the catalogue, and Fig. 4*b* and *c* shows the distribution of their separations in right ascension ($\Delta\alpha$) and in declination ($\Delta\delta$). By comparing the distributions as shown in these figures we find, as expected, more pronounced peaks in the ($\Delta\alpha$) distribution at separations of about 5 and 10 minutes, while the peak in ($\Delta\delta$) distribution is centered around zero separation, which indicates that a significant separation is lost because of the inaccuracy in this co-ordinate.

In an attempt to identify optically the suspected double image pairs, priority should be given to all eleven opposite pairs with a separation 10′ to 15′. If they have a displacement in both right ascension and declination corre-

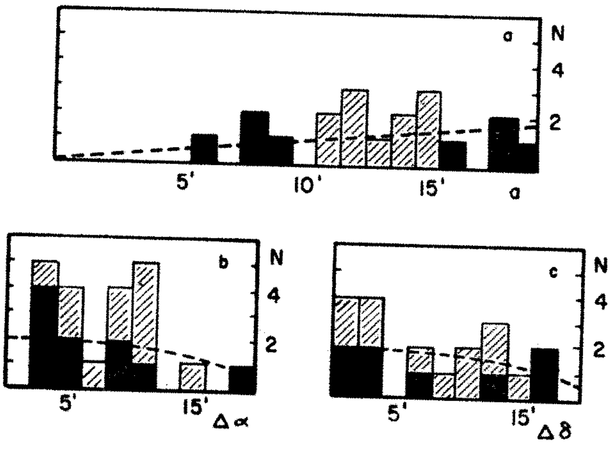

Fig. 4. *a*, The detailed distribution of close pairs in *R*. The excess seems to be concentrated in the separation range 10′–15′ (shaded). *b* and *c*, The same objects distributed due to the separation in right ascension ($\Delta\alpha$) and declination ($\Delta\delta$). The shaded objects are the same as in Fig. 4*a*. Expected distributions are shown as broken curves.

Table 1 MOST PROBABLE REAL OPPOSITE PAIRS

Priority 1	Priority 2	Priority 3
4C–04 02, 4C04 42	4C–05 08, 4C05 58	4C–02 62, 4C02 09
4C–04 07, 4C04 48	4C–04 58, 4C04 14	
4C–04 34, 4C04 77	4C–05 81, 4C05 32	
4C–03 40, 4C03 53	4C–05 87, 4C05 39	
4C–02 57, 4C02 03	4C–01 60, 4C01 29	

sponding to the excess distribution in these co-ordinates, we give priority 1 If they have excess in only one of the co-ordinates we give priority 2, and in none priority 3 The eleven pairs can then be sorted as shown in Table 1 Obtaining optical identifications of some of these pairs for closer study would enable us to decide if the observed effect is cosmological In particular, red-shifts of both members of pairs must satisfy a unique relation in order to satisfy the cosmological explanation

A programme for optical identification has been started at McDonald Observatory for a few of the most promising pairs, but it is likely that better radio positions will be necessary before any positive identifications can be expected

I thank G de Vaucouleurs for valuable suggestions

Nova Model of Centaurus *XR*-2

RECENT observations of the Centaurus region[1–3] have firmly established the existence of a variable X-ray source, Centaurus *XR*-2 This source is unique in that its variability has been established beyond doubt[2–4]

Francey *et al* [4] compared their data from two rocket flights in April 1967 with those of Chodil *et al* [2] obtained in May, 44 days later They found the data to be consistent with monotonic cooling of a thin plasma source from 4 2 ± 0 6 × 10⁷ °K to 1 8 × 10⁷ °K, accompanied by a five-fold decrease in the 2–8 keV energy flux during this period Data presented by Cooke *et al* [3] suggest a somewhat faster decrease

These observations, together with the assumption (supported by the detailed energy spectrum of Chodil *et al* [2]) of an optically thin X-ray source, suggest a model of the cooling X-ray source which is satisfied by the physical conditions expected[5,6] in a circumstellar envelope shortly after a nova outburst

At the observed temperatures, the radiation originates principally in electron proton bremsstrahlung The spectral intensity, j_E, at distance d from an isothermal thin plasma of volume V, containing n_e electrons/cm³, is then given by[7,8]

$$j_E\,\mathrm{d}E \sim (1\times10^{-28})\left(\frac{n_e{}^2V}{d^2}\right)T^{\frac{1}{2}}\left(\frac{\mathrm{e}^{-E/kT}}{kT}\right)\mathrm{d}E \text{ ergs/cm}^2\text{ sec}$$

where we take the gas to have the normal chemical abundances Using this relation we find that $(n_e{}^2V/d^2)$, initially about 5×10^{17} cm⁻⁵, had decreased by a factor of about 2 at the time of the Lawrence Research Laboratory rocket flight[2] 44 days (4×10^6 sec) later Assuming that the mass of radiating gas was conserved during this period, this at once implies a polytropic gas expansion, $TV^{\gamma-1}$ equal to a constant, with exponent γ equal to $2^{+1}_{-0\ 5}$. Although this is consistent with steady adiabatic expansion (γ = 5/3), isothermal motion (γ = 1), as proposed by Manley[9], is clearly at variance with the observations Tucker[6] has pointed out the difficulty of maintaining steady gas expansion through gravitational constraint at these high temperatures It seems highly probable therefore that the expansion was explosive and that the X-radiation originated in a shell of shock heated gas Before showing that the time decay of the source can be explained naturally in terms of an adiabatic blast wave propagating radially out through a circumstellar gas envelope, we note the following orders of magnitude

The gas temperature, (1 5–4) × 10⁷ °K, limits the radial expansion velocity to v about 10⁸ cm/sec Also, the mass conserving (n_eV = constant) volume change sets a radial expansion $\Delta R/R$ of order one over a period of 4×10^6 sec When first seen on April 4, the source was therefore no more than a month or so old, having expanded to a radius R_1 of about 5×10^{14} cm (30 astronomical units) An upper limit to the mean electron density of $n_e \leqslant 5\times10^8$ cm⁻³ then follows from the extreme assumption that the plasma cooled by radiation alone Taking $n_e = 10^8$ cm⁻³, we find a total mass (n_em_HV) of about 10²⁹ g (5×10^{-5} $m_\odot$) and an emission measure, $n_e{}^2V$, of about 4×10^{60} cm⁻³ on April 4 The thermal energy content, $3n_ekTV$, circa 10⁴⁵ ergs, and luminosity, L, ~ $10^{-27}T^{\frac{1}{2}}\,n_e{}^2V$, circa 10³⁷ ergs/sec, give a radiative life time of about a year and the distance to the source (from $n_e{}^2V/d^2$, ~ 5×10^{17}) becomes about 1 kparsec This distance may be regarded as an upper limit because there is no need to invoke significant radiative cooling, and the electron density may well be considerably lower than 10⁸ cm⁻³

These parameters are typical of those deduced for recurrent novae by Wallerstein[5] from coronal line measurements We now use the blast wave solutions of Rogers[10] in order to find a more detailed model of the expansion The cooling data for Centaurus *XR*-2 show that any such model must conserve the quantity $(n_e{}^2V/T)$ during the expansion This condition is satisfied for an adiabatic strong shock which propagated radially outward through a non-uniform gas envelope in which the density

$$n \propto r^{-\alpha} \text{ with } \alpha = 2$$

The shock wave solutions give the radius, R, of the shock front at time t as

$$R = kt^{1/\lambda}$$

and the velocity of the shock as

$$v = R/\lambda t$$

where λ is an expansion parameter which for an adiabatic shock is related[10] to α by

$$2\lambda = 5 - \alpha$$

Because $n_e{}^2 \propto R^{-2\alpha}$, $V \propto R^3$ and $T \propto v^2 \propto R^{2(1-\lambda)}$, we have $n_e{}^2V \propto T$ as required from the data, providing that

$$2\lambda = 2\alpha - 1$$

Thus

$$\alpha = 2$$

and

$$\lambda = 3/2$$

With this solution, the density behind the shock is a linear function of the radial distance from the origin of the explosion, increasing to $(\gamma+1/\gamma-1) = 4$ times the pre-shock envelope density at the shock front. The gas velocity similarly increases linearly with radial distance up to the shock boundary The emission measure, $n_e^2 dV$, falls off rapidly behind the shock front (as $(r/R)^4$), and we may take the effective X-radiator to be a nearly isothermal shell of thickness ΔR, about $R/4$, and volume $2 5R^3$, having the density, temperature and radius of the front

Because the 2–8 keV energy flux has suffered a six-fold decrease and the temperature, T, a 2 3-fold decrease in 4×10^6 sec, we find from $n^2 V \propto T \propto R^{-1}(t^{-2/3})$ that the shock wave would have been about 2 weeks old when first seen by the Universities of Adelaide and Tasmania group The shock wave temperature at that time determines an expansion velocity v of about 2×10^8 cm/sec and a corresponding shock radius of $R = \lambda tv$, about 3×10^{14} cm This would have increased to about 8×10^{14} cm when the source was seen by Chodil *et al* [2] The distance to the source becomes d about 300 parsec for $n_e = 10^8$ cm^{-3} and the energy of the blast, E about 10^{44} ergs

If the source is indeed an average nova at this distance, we might expect it to have reached a brightness greater than 4^m in March or April 1967 Some additional support for the nova hypothesis comes from the optically observed deceleration of nova envelopes[11] in which $v^2 \propto 1/R$ as in the present model of the X-ray source

In conclusion we note that the total X-ray luminosity decreases faster than t^{-1} even without radiative cooling, and that, 10^7 sec after the initial observation, the energy flux above 2 keV would have decreased by nearly two orders of magnitude

Extinction by Interstellar Silica Grains

INTEREST has recently been expressed in the possibility that the interstellar dust contains a silica component (ref 1, and R C Gilman, private communication) The purpose of this communication is to point out that silicon dioxide has strong absorptions in the 8–14μ atmospheric "window" which should be observable with ground-based infrared telescopes We have computed normalized extinction spectra (extinction cross-section divided by geometrical cross-section) for crystalline quartz and vitreous silica

The refractive index of quartz varies between 1 52 and 1 57 in the visible region of the spectrum To determine approximately the size of interstellar silica grains, we have compared the Mie calculation of Lowen[2] for $m = 1 55$ with the extinction curve of Boggess and Borgman[3] between 0 3 and 1 5μ A particle of radius 0 2μ gives agreement to 15 per cent over this range Although a single size model is probably too simple to describe the interstellar dust completely, this size should at least be indicative of the real situation

The extinction in the infrared by quartz spheres of radius a can be calculated by a generalization of the expressions given by van de Hulst[4]

$$Q_{\text{sca}} = \frac{8x^4}{9}\left[2\left|\frac{m_o^2-1}{m^2+2}\right|^2 + \left|\frac{m_e^2-1}{m_e^2+2}\right|^2\right] \qquad (1)$$

$$Q_{\text{abs}} = -\frac{4x}{3}\, Im\left[2\left(\frac{m_o^2-1}{m_o^2+2}\right) + \left(\frac{m_e^2-1}{m_e^2+2}\right)\right] \qquad (2)$$

where m_o and m_e are the ordinary and extraordinary complex refractive indices and $x = 2\pi a/\lambda$ For vitreous silica we have included terms in x^3 and x^4 in Q_{abs}, as given by van de Hulst (ref 4, p 270) Optical constants were obtained from refs 5–7 for quartz and from refs 5, 6 and 8 for vitreous silica The imaginary part of the refractive index between 2 7 and 7μ for both cases was calculated from the absorption data of Drummond[6] The results give a mismatch between these optical constants and those above 7μ

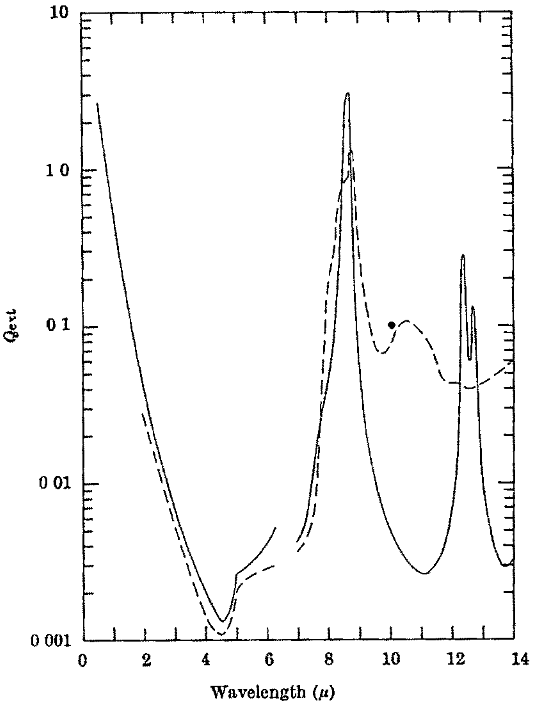

Fig 1 Normalized extinction cross-section for particle radius of 0 2μ ——, Quartz, - - -, vitreous silica

Results are shown in Fig 1, where Q_{ext} ($Q_{\text{sca}} + Q_{\text{abs}}$) is plotted against wavelength for particle radius $a = 0 2\mu$ Below 2μ where x becomes large, Q_{ext} is taken from the Mie extinction calculation of Lowen for $m = 1 55$ For quartz, the extinction at 8 7μ is 60 per cent of that at 0 6μ

Quartz is strongly dichroic in the double absorption at 12 6μ The ordinary ray is absorbed at 12·7μ and the extraordinary at 12 4μ This feature, apparently a property of the long range order of the crystal, is not evident in the vitreous phase The position of the absorption at 8 7μ is noteworthy The imaginary part of the refractive index has maxima at 9 3 and 9 2μ for the ordinary and extraordinary rays of quartz, but the extinction by small spheres is greatest at 8 7μ At this wavelength the real part of the dielectric constant m^2 approaches -2, so that there is a resonance in equation (2) A similar effect in metallic spheres has been described by Unsold[9]

PLANETARY SCIENCE

Precipitated Electrons as a Cause of the Irregular Behaviour of the F_2 Region

It has been established that electrons precipitated from the outer radiation belt produce ionospheric disturbances[1-3] Most of these were found to involve decreases in f_0F_2, suggesting that the fluctuations in precipitated electron flux will produce a spread in f_0F_2 values about the hourly means We therefore compared latitudinal and longitudinal variations in precipitated electron flux with similar variations in the root-mean-square deviation of f_0F_2

For the longitudinal analysis, a number of ionosphere stations lying along $L=4$ in the southern hemisphere were selected For the latitudinal analysis, five southern hemisphere stations lying over a fairly narrow range in longitude (about 140° E to 170° E) and extending from $L=1\ 5$ to $4\ 0$ were used The latter stations lie well outside the South Atlantic geomagnetic anomaly and so are not affected by this

Using the data for the three months November, December 1962 and January 1963, the root-mean-square deviation of f_0F_2 was calculated for each hour for the selected stations It sometimes happens that a value for f_0F_2 cannot be obtained In the event of a record being lost because of a total blackout, f_0F_2 was regarded as being at least as small as $f_{\min}$, which was estimated by interpolation In cases where the measurement of f_0F_2 was influenced by spread—F, absorption, atmospherics, etc — the observations were omitted from the count in calculating the root-mean-square deviation.

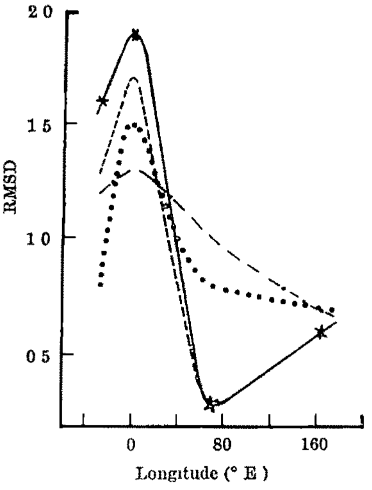

Fig 1 Longitudinal variations of the root-mean-square deviation (RMSD) of f_0F_2 (Mc/s) at different times of day ———, 00 LT, - - - , - - 06 LT, , 12 LT, — —, 18 LT

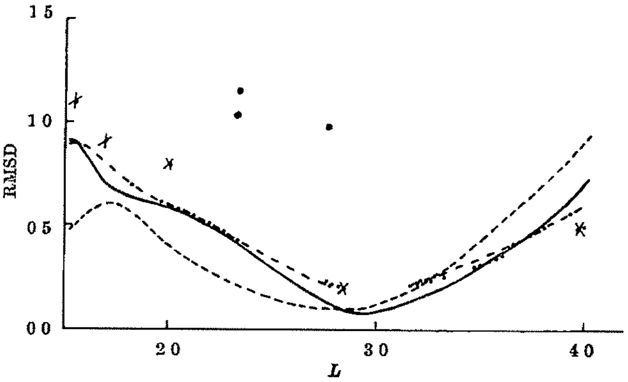

Fig 2 Variation of the root-mean-square deviation (RMSD) of f_0F_2 (Mc/s) with L at different times of day ———, 00 LT, - - - , 06 LT, , 12 LT, — —, 18 LT

Fig 1 shows a plot of the root-mean-square deviation against longitude for four southern hemisphere stations on $L=4$. The stations are Halley Bay (26 6° W.), Sanae (2 3° W), Kerguelen (70 2° E) and Campbell Island (169 1° E) Sanae and Halley Bay lie in the region where high intensities of charged particle fluxes have been observed[4,5] It is known that the intensity of precipitation of electrons is inversely dependent on B, the total geomagnetic intensity On $L=4$, B reaches its lowest surface value in the vicinity of Sanae We therefore expect precipitation of electrons to be greatest in this region and Fig 1 shows that the root-mean-square deviation is also greatest in this region.

Fig 2 shows a plot of root-mean-square deviation against L The stations in this case are Brisbane ($L=1\ 55$), Woomera ($L=1\ 70$), Canberra ($L=2\ 0$), Hobart ($L=2\ 85$) and Campbell Island ($L=4{\cdot}0$) There is a decrease in root-mean-square deviation at $L=3$ corresponding to the decrease in precipitated electron flux which has been observed at the same shell[6-8]

A further point may be briefly speculated on here. It can be seen in Fig. 1 that the curve for midnight shows a far more pronounced longitudinal variation than that for mid-day It has recently been suggested[9-12] that atmospheric winds result in ionosphere drifts having a vertical component which is usually downward during the day and upward during the night It is therefore possible that at night the ionization produced by the incoming electrons be blown upward into a low loss rate region, magnifying the effect

Evolutionary Processes and Reversals of the Earth's Magnetic Field

It has been suggested that there is a connexion between reversals of the Earth's magnetic field and evolutionary processes[1-3]. This topic has excited much interest since the discovery of an apparent correlation between levels of field reversal and microfaunal discontinuities in deep sea sediment cores[4]. The Earth's magnetic field is known to have reversed its polarity at least nine times during the past 4×10^6 yr[5,6] and at frequent intervals before that except during the Permian[7]. Briefly, the ideas of Uffen[1,2] and Simpson[3] are that during the process of a reversal there is a period of reduced or zero intensity of the dipole field during which there should be a great increase of cosmic radiation at the Earth, which is no longer shielded by its magnetic field. This enhanced radiation will produce a higher mutation rate, which will result in some kind of evolutionary discontinuity. There is good evidence that during the process of reversal, the Earth's dipole field is reduced in strength, probably passing through zero[4,8]. The other assumptions are less acceptable.

Organisms receive radiations from many different sources[9] (Table 1). Of those listed in Table 1, a change in the intensity of the Earth's magnetic field will change only the radiation from cosmic rays and carbon-14.

Table 1. DOSE RATE IN MILLIREMS/YR ON HUMAN GONADS*

	Source of radiation	Dose rate
External	Cosmic rays	50
	Terrestrial (from rocks, etc.)	50
Internal	Elements of radium and thorium series	5
	Potassium-40	20
	Carbon-14	1

* Because we are interested in mutations, the gonadal dose rate is appropriate.

Primary cosmic rays consist of protons with energies between 10^7 and 10^{20} eV (ref. 10). The Earth's magnetic field deflects cosmic rays and produces a shielding at the Earth which is dependent on the horizontal component of the field. Above the atmosphere it is found that the cosmic ray intensity is reduced by a factor of about ten on going from (magnetic) pole to equator. At the bottom of the atmosphere, the latitudinal change is only 14 per cent[11]. This is because the atmosphere absorbs the low energy cosmic rays which are those chiefly responsible for the large latitudinal effect above the atmosphere.

Lingenfelter[12] has estimated that the present polar carbon-14 production rate (attributed to cosmic rays) is not more than 2.1 times the average global production. So, on the assumption that during a reversal the whole Earth receives the present polar cosmic ray intensity, we can estimate that the equatorial dose rate caused by cosmic rays should increase from 50 to 57 millirems/yr and that the dose caused by carbon-14 should increase from 1 to 2.1 millirems/yr. This is an increase of 16 per cent.

If the Earth's dipole moment were larger than at present, the latitude effect would be greater. There have undoubtedly been variations in the Earth's magnetic field strength. Studies of the palaeofield intensity show that the field has probably not been more than 1.5 times its present intensity for significant lengths of time and that it was less intense during the Tertiary[13,14].

To calculate the shielding effect of a larger field, Table 3 from Compton[11] has been used. The geomagnetic latitude (for latitudes less than 45°) was converted to horizontal field strength and this was plotted against cosmic ray intensity (Fig. 1). Assuming that the shielding is directly proportional to horizontal field strength, the regression line shows that if the field strength were 1.5 times the present strength, the equator would receive 65 per cent of the polar dose. During a reversal the equatorial dose rate would therefore change from 37 to 57 millirems/yr because of cosmic rays, and from 0 to 2.1 millirems/yr (at the most) because of carbon-14. This gives a total change from 37 to 59.1 millirems/yr or an increase of 60 per cent.

Mutations are produced by radiation, chemical effects and errors in replication. Cosmic rays produce only a small percentage of all observed mutations. For example, it has been estimated that the total mutation rate in humans is equivalent to that which would be produced by 100 rems/generation[15,16] or 3.3 rems/yr. This is known as the doubling dose. Even in the case of a field 1.5 times the present field intensity, the change in mutation rate when the field goes to zero will be only 0.6 per cent at sea level on the equator. This seems much too small to cause an evolutionary discontinuity.

The doubling doses for mice[9] and *Drosophila*[17] are somewhat greater than for humans and, because of the much shorter generation length for these organisms, the effect of a reversal of the Earth's field will be minute. In general, it is extremely unlikely that a reversal of the Earth's magnetic field could have anything but a small effect on the mutation rate of organisms living at sea level unless these organisms have a much lower spontaneous mutation rate than humans, mice or *Drosophila*.

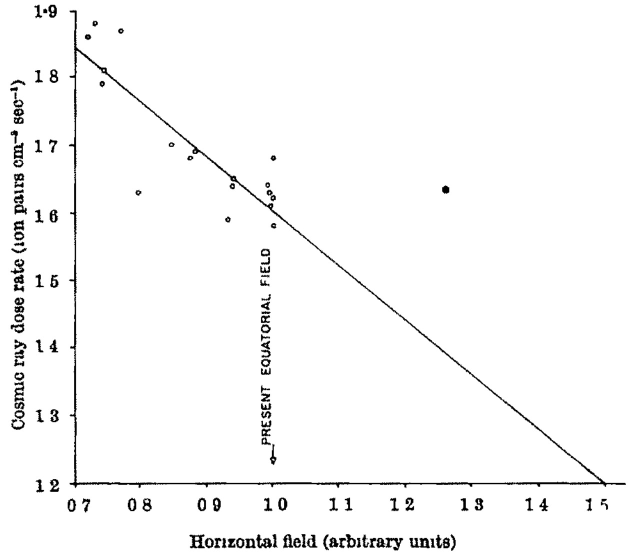

Fig. 1. Variation of cosmic ray dose rate with horizontal field intensity. The points are taken from Compton[11]. The least squares regression line is shown. Correlation coefficient = −0.8668.

It has been suggested that the present atmosphere is the result of a slow degassing of the rocks forming the Earth which has been occurring throughout geological history[18]. Although this could lead to an increase of the latitude effect at sea level further back in time, it is undoubtedly counteracted by the decrease in the strength of the Earth's magnetic field[13].

Despite these arguments, it does seem that there may be a correlation between evolutionary discontinuities and reversals of the magnetic polarity in deep sea cores[4]. These cores all came from latitudes greater than 40°, where the change in the cosmic ray intensity during a reversal would be much less than at the equator. One possible cause for such a correlation might be a climatic change at the time of a reversal. I can suggest two possible mechanisms whereby a reversal could cause a climatic change.

First, there seem to be several meteorological effects which are to some extent controlled by the Earth's magnetic field. King and Kohl[19] and King-Hele and

Allan[20] have suggested the importance of the Earth's magnetic field in controlling the wind velocity near the top of the F layer What the effect of removing the dipole field would be, and whether this effect could change the climate of the Earth, have not been studied Jacchia and Slowey[21] state, "It looks as though the role of the magnetic field of the Earth in controlling the temperature of the upper atmosphere might be considerably more important than was supposed heretofore"

Second, although the latitude effect at sea level is only about 14 per cent, above the atmosphere it is much greater[12] The result of removing the Earth's magnetic field would be to increase several times the amount of ionization produced in the atmosphere by cosmic rays, and also by the solar wind It seems that between altitudes of about 50 and 80 km the main source of ionization today is cosmic radiation[22] It is possible that a large increase in the ionization at this level could have an effect on the climate

During a reversal of the Earth's magnetic field, organisms at the equator will receive about 14 per cent more cosmic radiation than they do at present. Because of the comparatively high spontaneous mutation rate of organisms studied so far it is extremely unlikely that this increase in radiation could have a significant effect on mutation rates It is suggested that a possible cause of the correlation between microfaunal discontinuities and reversals should be looked for in a climate change Climatic changes could be brought about because of the control that the Earth's magnetic field may have on meteorological phenomena, or because of an increase of ionization at certain levels in the atmospheres These are only suggestions and it would require investigation by meteorologists to ascertain if the climate could be affected in such a way.

I thank Dr L E Orgel, of the Salk Institute, and Mr H P Sleeper, of Ryan, for several helpful discussions. Some of this research was done while I was at the Scripps Institution of Oceanography Support for this work was received from the US National Science Foundation and the US Office of Naval Research

Group Analysis of Variance for Earthquake Location and Magnitude

Two central problems in seismology are the location of earthquake epicentres and the allocation of magnitudes to earthquakes We show in this communication that these problems can be reduced to the classic statistical model of two-way analysis of variance Applying this theory to the reduction of pooled data from many stations and earthquakes leads to estimation of source and station terms and the interaction between them In particular, it provides the theoretical framework for the method of group (or regional) adjustment of epicentres used by Freedman[1] and Douglas[2] The embedding of the problems in this theory opens the way for strict statistical tests of various hypotheses of geological interest

Consider I seismic regions and J seismological stations Arrange the measurements under study into a two-way layout in which the "i, j cell" contains the measurements from region i (i = 1, 2, I) at station j (j = 1, 2, J) For simplicity, suppose that no cell is empty (Approximate methods of dealing with a layout with empty cells are discussed by Freedman[3]) Denote the number of measurements in the "i, j cell" by K_{ij} (K_{ij} = 1, 2, K)

First, we examine the analysis of the layout for the earthquake location problem Let r_{ijk} denote the travel time residual (for the P wave, say) from the kth earthquake (k = 1, 2, . . K_{ij}) in the ith seismic region, to the jth station, let η_{ij} denote the cell mean Now the main effect, α_i, of the ith region is the excess of the ith row mean, A_i, over the general mean, μ, of the residuals, that is, $\alpha_i = A_i - \mu$ In seismological terms, α_i is the average source adjustment Similarly, the main effect β_j of the jth station ($\beta_j = B_j - \mu$) is the average adjustment ("station correction") for the jth station

There is now strong evidence that P residuals at many stations vary markedly with azimuth[4] One functional relation used is

$$h_j(\theta) = \beta_j + D_j \sin (\theta + E_j)$$

where θ is the (station to source) azimuth and D and E are constants (Recent work with data from Californian stations indicates that, for some stations, this representation is too simple, the function may be discontinuous)

Azimuthal variations, at both source and station, give rise to interactions, that is, the observed variation in travel times contains a term $\gamma_{ij}(\theta)$ which measures the effect of the ith seismic region at station j over and above the main effect α_i of the region, that is

$$\gamma_{ij}(\theta) = \eta_{ij} - \alpha_i - \beta_j - \mu$$

The term $\gamma_{ij}(\theta)$ may be interpreted as the combined source and station azimuth anomaly function, where for simplicity the dependence on epicentral distance (angle of emergence) has been ignored (The interpretation of the argument θ needs care, it might be azimuth of station to source or vice versa)

Because hypocentral locations are computed so that average P residual is close to zero, the overall mean μ, for a group of earthquakes, will be close to zero Then, if the errors involved are both independent and normally distributed about zero mean with common variance (that is $N(0, \sigma^2)$), the travel time problem is reduced to the classic model of two-way analysis of variance Devices must be applied to minimize any non-normality in the distribution of errors For example, contaminations such as extreme residuals can often be dealt with by Jeffreys' method of uniform reduction[5]

The least squares estimates (assuming equally weighted observations) for the source and station adjustments can then be simply calculated The azimuth anomaly function is estimated by

$$\gamma_{ij} - r_{ij} \quad - r_{i} \quad - r_{j} \quad + r_{\bullet}$$

where a dot indicates that the arithmetic mean has been taken over that subscript. As an illustration, the analysis of variance model may be used to test whether the β_j for stations in one continental region are significantly different from those in another The mathematical formula and methods are given, for example, by Scheffé[6]

This general theory shows at once why it is advantageous in epicentral determinations to combine earthquakes into regional groups during the calculations The underlying idea is that the error distribution arises from errors in reading the time of arrival, t_{jk}, of the P phase Thus separation of the source and station terms by appropriate averaging allows the variations in the reading errors to be reduced to nearly zero.

Consider a particular seismic region with K earthquakes (we now suppress the suffix i) selected so that the true station residual against the global tables $r_{jk} = r_j = r(\Delta_j)$ Apart from an additive constant, the M residuals $r(\Delta_j)$, for M ranges of distance, can be estimated if necessary along with the epicentral adjustments For brevity, we simply combine the source and station terms so that $g_j(\theta) = \alpha_i + \beta_j + \gamma_{ij}(\theta)$ Then the standard linearized equation[1] for the location of the kth earthquake is

$$\hat{r}_{jk} = r(\Delta_j) - \delta\tau_k - a_{jk}\,\delta x_k - b_{jk}\,\delta y_k - \delta g_j(\theta) + \delta t_{jk} \qquad (1)$$

where τ is the origin time, x is longitude, y is latitude, $a = \dfrac{\partial t}{\partial \Delta} \sin \hat{\theta}$, $b = \dfrac{\partial t}{\partial \Delta} \cos \hat{\theta}$, and Δ is the epicentral distance In this equation, the focal depth term has been ignored and δ is used to denote adjustment to provisional values

Assuming that the errors δt_{jk} are independently $N(0, \sigma^2)$, an analysis of variance yields the adjustments $\delta\tau_k$ δx_k δy_k for the K earthquakes as a group as well as δg_j and $r(\Delta_j)$ (Formulae are given by Freedman[1] in a more restricted case than given here) There are $J+3K+M$ unknowns and JK equations of condition

In a numerical test of the method, P travel times to five stations of the Berkeley network from the two Bikini atomic explosions Bravo and Union with known positions and shot-times were used The co-ordinates were interchanged but the shot-times kept fixed The longitude change was 0 114° and the latitude change 0 036° A relocation, using the foregoing method, shifted, with the correct signs, the latitudes by 0 04° and the longitudes by 0 09°

In the published example by Douglas[2], times at thirty stations from six earthquakes and the explosion Longshot in the Aleutian Islands are used to make a group (or joint) location The stations were well distributed with azimuth The estimated position of Longshot was much closer to the known shot-point than when a location was made for Longshot alone The previous theory provides the explanation without the separate estimates of the $\delta g_j(\theta)$ terms, the error terms are non-normal

It should be remarked that Douglas does not make clear the full complexity of his "station correction" term A comparison between his equation (2) and our equation (1) shows that the numbers which he computes are estimates of the sum of the station and source adjustments (relative to the Jeffreys–Bullen tables) as well as an interaction term which may be azimuthally dependent As a consequence, the numbers assigned as "station corrections" apply only for the selected group of earthquakes

The way now appears open, using analysis of variance techniques, for more reliable location of earthquakes Regional and global seismological centres doing routine hypocentral determinations can easily adapt the group method to their special requirements It would seem wise if a calibration event be included when possible in each group calculation Underground nuclear explosion, well located earthquakes or, for local networks, a timed quarry blast would all serve Any regional bias in location, perhaps caused by poor azimuthal distribution of stations, could in this way be detected On this point, solutions are not optimized by using readings from all available stations, on the contrary, some uniform azimuthal distribution should be used

Finally, the group method outlined here seems promising also for the routine estimation of the magnitudes of both teleseisms and local earthquakes In place of time residuals, consider measurements from seismograms of $\log_{10}(A/T)$, denoted by $\hat{a}_{jk}$, where A is the amplitude of a wave of period T The computed magnitude of the kth earthquake at station j is $\hat{M}_{jk} = \hat{a}_{jk} + q(\hat{\Delta}_{jk})$, where q is some standard function[7] For a particular region, equation (1) is replaced[8] by

$$\hat{M}_{jk} = M_k - \delta q(\Delta_j) - \delta g_j + \delta a_{jk} \qquad (2)$$

in which M_k denotes the true magnitude of the kth earthquake, δa_{jk} is the reading error, δq is the correction needed to the standard distance term and δg_j, as before, denotes the combined station and regional source adjustments (including azimuthal interactions)

Simultaneous computation of the magnitudes of K earthquakes from measurements at J stations will provide maximum likelihood estimates of M_k, $\delta q(\Delta_j)$ and δg_j if the errors are independently $N(0,\sigma^2)$ Because the formulation (2) allows the calculation of the systematic station-source terms δg_j separately from the random variation, the assumption is likely to be a reasonable one Suppose $q(\Delta_{jk})$ be considered in N piecewise constant segments, then the analysis of variance would require the solution of JK equation with $J+K+N$ unknowns

Late Tertiary Slumping on the Continental Slope of Southern Portugal

THE geological relationship of the Atlantic Ocean to Europe is recorded west of the British Isles and France in a sequence of continental shelf and slope deposits, although the latter seem to be missing on the northern and western sides of Iberia[1] Accordingly, the southern continental slope of Iberia was examined (Fig 1) for the missing parts of the record, particularly south of Portugal where a detailed bathymetric survey had revealed a series of long, sub-parallel ridges with a westerly to west–south–westerly trend (Hydrographer of the Navy, personal communication)

The examination was made from RRS Discovery by a continuous reflexion profiler, using a modified airgun of Lamont type as the sound source The peak pressure at its face was 1×10^6 dyne cm^{-2} at a distance of 1 m The amplifier and hydrophone were built to a National Institute of Oceanography design The preferred hydrophone was 50 ft long with ten elements spaced to taper the beam, so reducing the side lobes and presenting maximum sensitivity to the sea floor at the frequencies used The two profiles illustrated have been traced directly from the originals, which were recorded on a modified Mufax recorder

The records showed that the continental slope, south of Portugal, is composed of folded, well bedded sediments at least 0 6 sec thick, equivalent to more than 2,000 ft at a compressional velocity of 6,560 ft sec^{-1} (ref 2) The folds observed bear an intimate relationship to the relief, such that the anticlinal and synclinal axes correspond exactly with the axes of the ridges and troughs (Fig 2 and profile *a*–*b* of Fig 4) Further east, a profile (Fig 3 and profile *d*–*e* of Fig 4) extending almost along the strike of the folds shows that the folds have been buried by the Quaternary continental shelf and upper slope sediments South of Portugal (Fig 2) the absence of sediment fill in the synclines can be ascribed to the large canyons, which transect the folds, acting as paths for the transport of sediment to deeper water

The distribution of folds, shown by the profiles and extrapolated from the relief, is illustrated in Fig 4 There is a general southerly decrease in wavelength and increase in amplitude to a maximum of 1,200 ft as well as a change in trend from westerly to west–south–westerly The belt of folded sediments is terminated to the south by an area of gentle gradient and irregular topography which exhibited a very high reflectivity and beneath which no bedding was seen This area is believed to be the submerged extension of the highly contorted and metamorphosed rocks of the Betic Alps, the development of which culminated in the Burdigalien

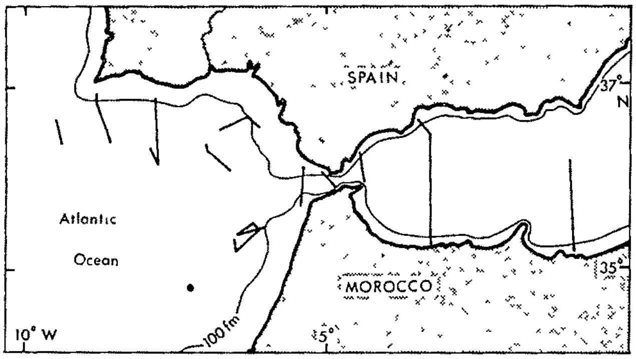

Fig 1 Location of continuous reflexion profiles obtained by RRS Discovery south of Iberia

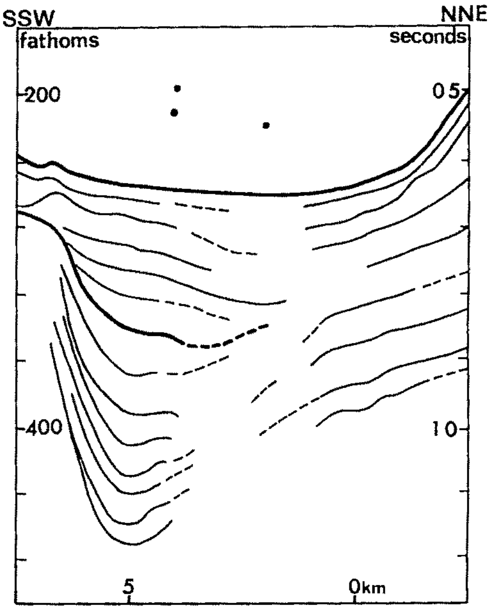

Fig 3 Continuous reflexion profile (*de* of Fig 4) showing the burial of folded sediments (upper surface shown by a heavy line) at the base of the Quaternary continental slope

The gentle folding of the late Tertiary sediments might have been produced by a north–south compression between the principal tectonic units of southern Spain

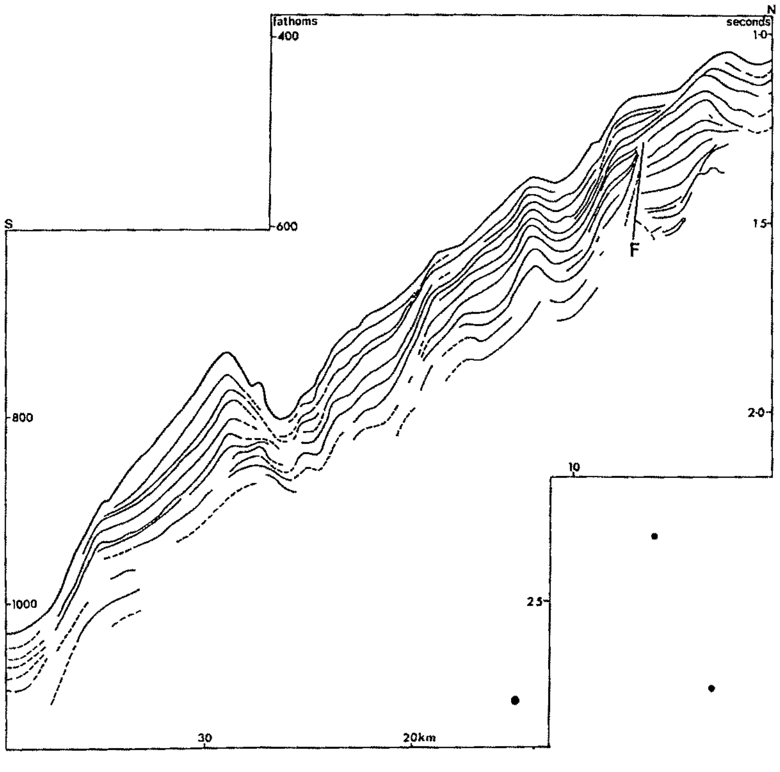

Fig 2 Continuous reflexion profile south of Portugal (*ab* of Fig 4) showing the close relationship of folds to relief *F* Fault zone Note the absence of sediment fill in the troughs

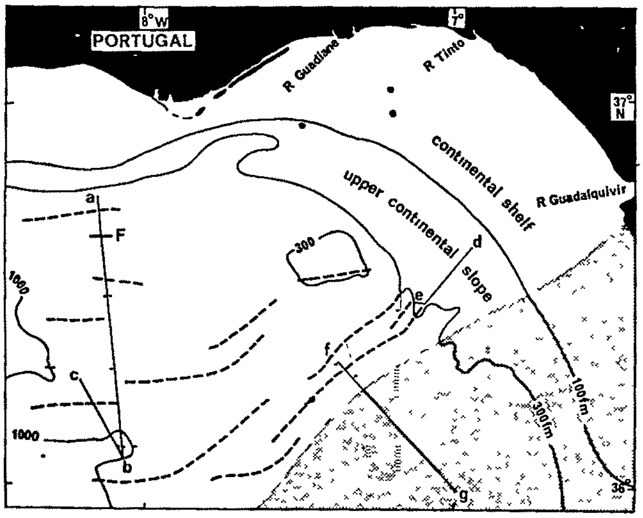

Fig 4 Distribution of slump folds (anticlines ----, synclines) from reflexion profiles *abc*, *de* and *fg* and inferred from the relief *F* Fault zone Shaded area is the supposed submarine extension of the contorted and metamorphosed rocks of the Betic Alps

and Morocco (Fig 1) The change in fold style downslope and the absence of complementary folds in the western Mediterranean, however, are not in agreement with such a mechanism The preferred explanation is that the sediments, which had accumulated on the continental slope south of Portugal, were given an enhanced oceanward dip during the Pliocene uplift of Iberia and consequently moved downslope by creep and crumpled against the submerged northern edge of the Betic block (shaded in Fig 4)

The same episode of slumping may be partly responsible for the apparent absence of continental slope deposits on the northern and western sides of Iberia It is possible that slumping on existing continental slopes and those of the geological past is more generally associated with regional uplift of continents than has previously been supposed

We wish to thank the master and officers of RRS Discovery and our colleagues for their willing co-operation at sea, D G Bishop and A R Stubbs for their work on the continuous reflexion profiling equipment and N Kenyon for his valuable discussion.

Radio Emission from Geomagnetically Trapped Particles

Many experiments to measure the radio noise intensity in the topside ionosphere have found an intense "band" of noise in the range of frequency between the plasma frequency and the upper hybrid resonance frequency[1-4] Various explanations have been suggested, including plasma instability, radiation by energetic particles[5] and anomalous behaviour of the antenna impedance[4] Data received by the *UK*-2 (*Ariel* 2) satellite suggest that the energy for this noise comes from the particles trapped in the inner Van Allen radiation belt

The *UK*-2 radio astronomy experiment has been described elsewhere[3,6] A 40 m dipole antenna was connected to a receiver with an input impedance of 10 kΩ and a bandwidth of 20 kHz, and the frequency of reception was varied linearly between 0 65 and 3 50 MHz once every 28 sec The satellite orbit had an inclination of 51° and an apogee of 1,385 km

In the experiment reported here, the noise bands were of three principal types (1) noise between the plasma frequency and the upper hybrid resonance frequency, as already mentioned, (2) anomalously intense noise below

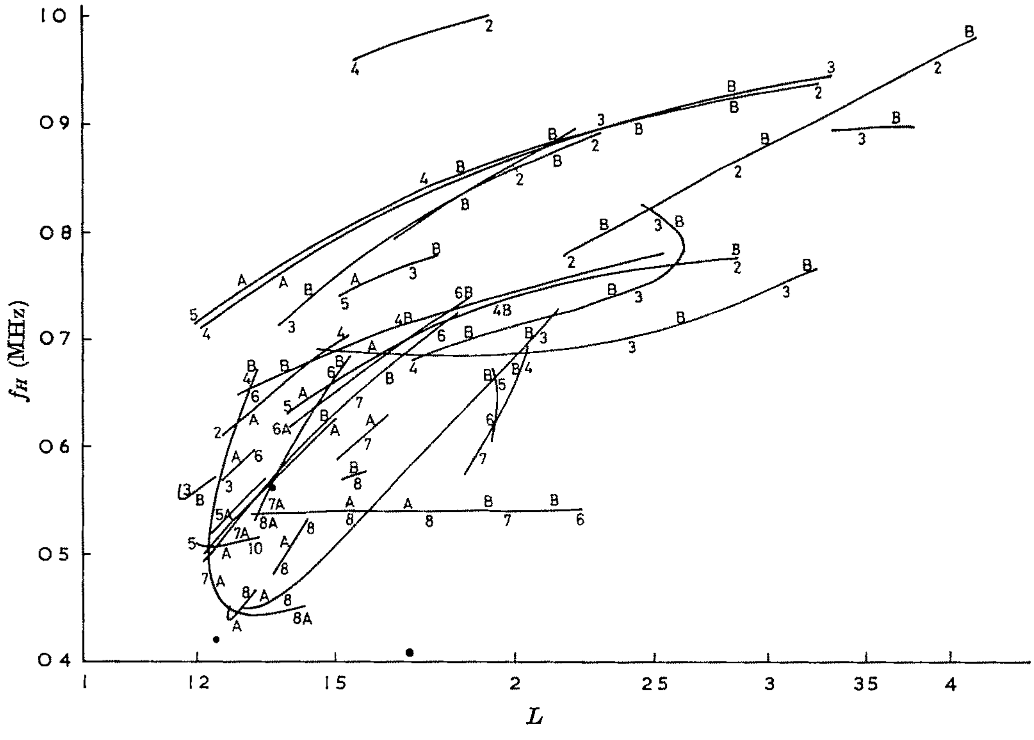

Fig 1 The trajectories of passes near to apogee plotted in *B*/*L* space, *B* being measured in terms of the gyro frequency for electrons

the local plasma frequency and above the extraordinary wave cut-off frequency, (3) low frequency noise with no definite cut-off frequency

I have examined in detail the interference-free passes near to apogee The trajectories of these passes in B/L space[7] are shown in Fig 1, B is measured in terms of the gyro-frequency for electrons Beside the curves are numbers representing the intensity of the noise band of type (1) It will be seen that the intensity is a maximum near the value $L = 1\ 35$ This is the position of the maximum energetic particle intensity in the inner Van Allen radiation belt[8]

A ray tracing programme has been used to show that electromagnetic waves cannot propagate over many degrees of latitude in the frequency range of the noise of type (2); this noise must be generated close to the point where it is observed The occurrence of this type of noise is qualitatively marked in Fig 1 A is written where it is observed, and B where it is not observed It is always observed near to the equator at $L = 1\ 35$, and never at points far from these co-ordinates

The noise of type (1) is used to determine the plasma and gyro frequencies at the satellite, and the latter frequency usually agrees well with the value calculated from a 48 coefficient spherical harmonic expansion of the geomagnetic field[9] Sometimes the agreement is rather bad this disagreement happens only at points well removed from $L = 1\ 35$

This evidence strongly suggests that the source of energy for the noise of types (1) and (2) is the particle radiation of the inner Van Allen radiation belt

PHYSICS

Duration of Sensitive Period for Track Recording in Mica

THERE is evidence which suggests that the tracks of muons and of electrons in electron showers may leave detectable marks in muscovite mica during a sensitive period following crystallization of the mica[1,2] The observation that the tracks of electrons may in special conditions leave detectable records suggests that mica is responsive to particles of low specific ionization during the sensitive period Consequently, charged particles of higher specific ionization such as alpha particles and fission fragments would also be expected to leave detectable records

It has been suggested that observable tracks of charged particles may be produced in mica as a result of the exsolution of an excess iron content on nucleation centres, formed by ionization of the crystal structure by the charged particles[1] Following the initial precipitation of the iron impurity at a nucleation centre, decoration of such centres will occur as a result of accretion of the impurity as exsolution continues The original nature of the initial precipitation will be masked to a considerable extent by the continued decoration For example, the individual dots delineating the track of an electron are commonly of the order of 1,000μ in diameter, while the track length of an alpha particle from natural nuclear decay is typically 25μ Indeed, the appearance of a fully decorated alpha track is unlikely to retain any of the initial characteristics such as direction of track or recordable length, only the fact of occurrence and general location being important As decoration of such a track continues, the crystal is liable to local fracture resulting in a characteristically star-shaped figure resembling a "percussion" figure, as would be expected

Fortunately, most crystals contain trace amounts of the naturally radioactive elements, and so isolated regions showing decoration by the iron impurity would be expected in mica specimens showing staining If the occurrence of such decorated regions or spots can be related to the radioactive impurity content, then the duration of the sensitive period of the mica for the recording of the passage of charged particles can be found for each specimen of mica

The occurrence of isolated regions of decoration or "spotting" in muscovite mica is well known A rough estimate of the duration of the sensitive period is made next Typically, muscovite mica may contain uranium and thorium in concentrations of a few parts in 10^9, or about 10^{13} atoms of uranium-238/cm^3 In every thousand decays, about one will lie sufficiently close to the (001) plane of the mica to be recorded, so in each year there should be about ten recordable alpha decays The density of these spots is roughly 100/cm^3, suggesting that the sensitive period lasts for something like 10 years

Measurements on these spots have been restricted to those regions also showing line staining, that is, decorated crystal defects and tracks In Fig 1 a plot is shown of the size distribution of these spots The observed distribution can be explained by assuming a two-dimensional growth of decoration on nucleation centres formed by tracks of alpha particles from natural nuclear decay together with a constant rate of exsolution of iron impurity Although fission fragments should also produce nucleation centres, the low probability for spontaneous fission relative to alpha decay makes this a negligible contribution It is well known that the spots are essentially flat disks with

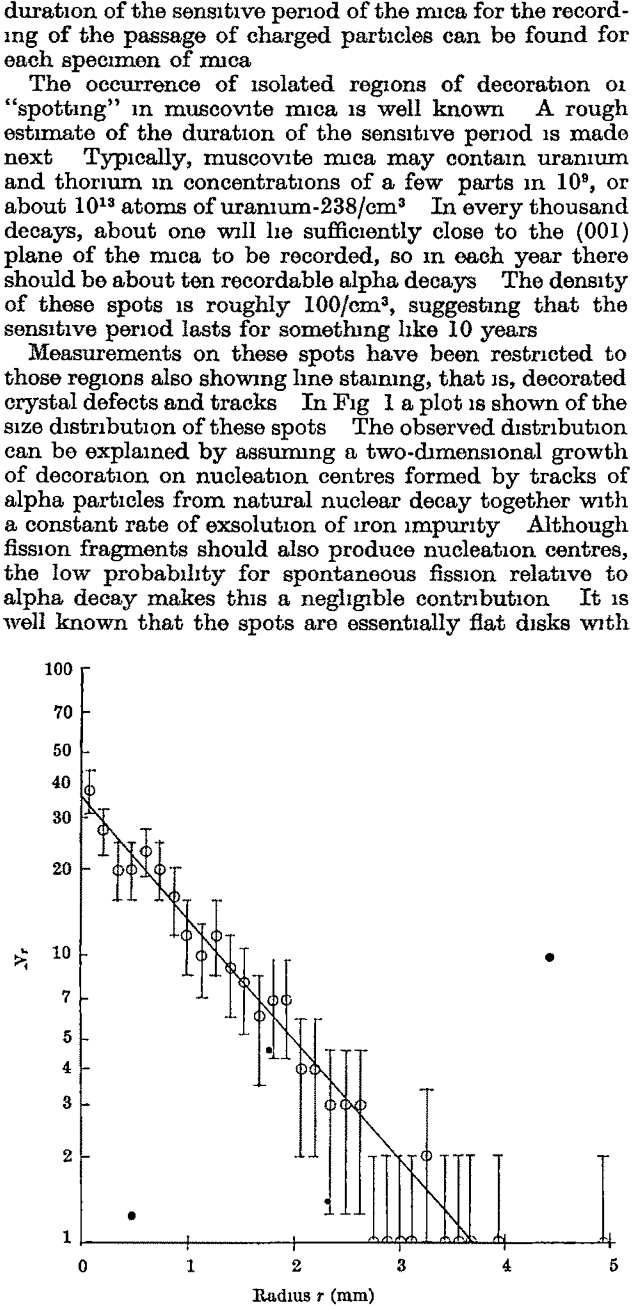

Fig 1 Plot of the mean radius of decorated spots in muscovite mica N_r is the number of spots occurring within a 100μ interval of radius

nearly constant thickness, so that growth must occur principally at the periphery, giving a two-dimensional growth by diffusion The details of the exsolution process are not known, but it is not unreasonable to assume that once exsolution has started it continues at an approximately constant rate until terminated by depletion of the impurity Because the change in temperature associated with the exsolution stage is probably small, it is also probable that the rate of diffusion changes only slightly during the sensitive period.

At the high temperatures involved, although mica is still essentially an insulator, the ionization produced by the passage of a charged particle will not persist for long, so that only those decays which occur after exsolution has started can form recordable nucleation centres On the short time scale involved, the number of nucleation centres will thus increase approximately linearly with time so that the amount of impurity available to each centre will decrease as more centres are formed Let r be the mean radius of a spot and q the quantity of impurity contained within the spot It follows that for a given rate of exsolution,

$$\frac{\mathrm{d}q}{\mathrm{d}t} = \text{constant} \quad \frac{r}{N}$$

where N is the number of centres present Because $2\pi r^2 \alpha \int \mathrm{d}q$ and N is proportional to t for small t, then

$$\frac{\mathrm{d}r}{\mathrm{d}t} = K\frac{1}{t}$$

giving the radius of a spot, formed at t_1 with decoration terminating at t_2, as

$$r = K \log (t_2/t_1)$$

The size distribution is then $\mathrm{d}N/\mathrm{d}r = Ce^{-r}$ where C is a constant and is shown in Fig 1 by the solid curve

A third reason for relating these spots to alpha decays is the observed correlation of spot density with concentration of uranium Because the duration of the sensitive phase of the mica is relatively short, it is probable that most of the alpha decays result from the thorium series The chemistry of thorium and uranium, however, has enough in common to permit a reasonable estimate of the thorium content from the measured uranium content The concentration of uranium in the specimens was determined by counting the number of fission tracks intersecting a given surface area of crystal after irradiation of the specimens in a known flux of thermal neutrons, the fission tracks being rendered observable by etching[3]. A definite correlation between spot and fission track densities has been observed (Fig 2)

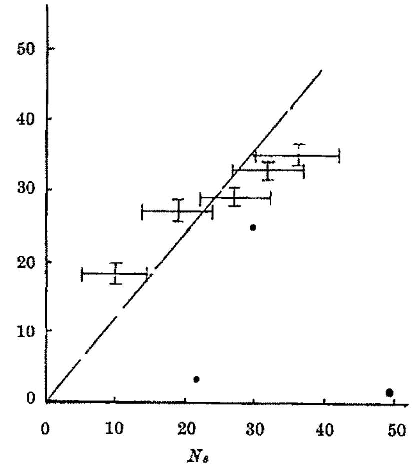

Fig 2 Correlation plot between the number of spontaneous fissions, N_f, and the number of spots, N_s, per unit of area, for a sample of mica showing considerable variation in the spot density

To determine the duration of the sensitive phase from the observed density of spots/unit volume requires a knowledge of the radioactive impurity concentration and of the mean detection efficiency of the mica to alpha particles The relatively long half-life of the uranium-234 alpha decay mediates the uranium-238 series so that only one alpha particle is associated with each uranium-238 decay In the thorium series, however, the relatively short half-life of radium-228 is the mediating element and more than one alpha particle is to be expected from each thorium-232 decay site during the sensitive phase The maximum number of alpha particles from each thorium-232 decay site is six, all with energies of 4 MeV or more Although the mean probability that any one will produce a nucleation centre is approximately the same, once a nucleation centre has been formed at a given decay site further alpha decays would be ineffectual On the average, the number of alpha particles from each thorium-232 decay site effective in producing new nucleation centres will be half the maximum From the known terrestrial thorium to uranium abundance ratio, the average number of alpha particles effective in nucleation centre formation, after allowing for the longer half-life of thorium-232 compared with uranium-238, per uranium-238 decay, is approximately three Finally to determine the mean detection efficiency it is necessary to specify the magnitude of the effective cut-off angle out of the (001) plane within which tracks of alpha particles may be recorded A lower limit for this angle is provided by the value pertaining to low energy muons namely about 2 milliradian Even though the specific ionization of fission fragments greatly exceeds that of alpha particles and so there may not be any restriction in angle for spot formation the half-life for spontaneous fission of uranium-238 is such that only a small fraction of the nucleation centres could arise from this cause

From measurements made on some mica samples from the Madras region of India, the duration of the sensitive phase was found to be about 16±8 yr The principal uncertainty is in the magnitude of the cut-off angle for alpha particles, and has been set by assuming the angle is proportional to the specific ionization The effect of this uncertainty is mitigated by the compensating influence of the radium-228 half-life In the other sense it is unlikely that the sensitive time for the recording of muons exceeds that for alpha particles

Because mica of the type considered here is usually associated with zoned pegmatites, the pegmatites being intrusive into the country rocks, a time scale of the order of a few tens of years is not unreasonable because this is commensurate with the probable growing time of the mica crystals It is not known yet whether the entire crystal becomes sensitive or only a small portion, perhaps close to the growing surface, the integrated sensitive time in either case being the same.

Acceleration Produced Electric Fields in Charcoal Bodies

An analysis of the electrodynamics of accelerated charged bodies reveals a new method by which Einstein's principle of equivalence may be tested If a uniformly charged spherical shell of radius r is given an acceleration a, there will be within it a uniform electric field E along the direction of acceleration the magnitude of which is given by

$$E = -\frac{q}{r\,c^2}\,a$$

This may be seen as follows[1] The scalar potential φ within the shell is constant The vector potential A which exists within a shell moving with velocity V is also constant This may be derived by Lorentz transformation of the static case with the result,

$$A = \varphi\frac{v}{c} = \frac{q}{rc}\,v$$

to first order in v

The retardation of the vector potential may be neglected for an accelerated shell provided

$$|a| \ll \frac{c^2}{r}$$

The acceleration produced electric field is obtained from the relationship

$$E = -\nabla\varphi - \frac{1}{c}\frac{\partial A}{\partial t}$$

Therefore $$E = -\frac{q}{r\,c^2}\,\dot{V} = -\frac{q}{r\,c^2}\,a$$

If, instead of an insulating shell, a charged conducting body of arbitrary shape were accelerated, the same phenomenon would occur, although the field might then be annulled by a redistribution of charge on the surface of the object

Schiff and Barnhill[2] have also derived an electric field which may be produced in metals in an acceleration field, but their field is independent of the excess charge in the body Provided that the scalar potential is constant within the accelerated object, the electric field produced by acceleration will be uniform and therefore conservative That is, the integral of electric field strength around any closed path is zero

$$\oint E\,\mathrm{d}l = 0$$

Permanent potential differences can be produced by placing two dissimilar metals in contact and utilizing the contact potential phenomenon[3] In this case, non-conservative electric fields can arise from which energy can be extracted if a current flows around a suitable path A case of interest is shown in Fig 1

The internal electric fields produced by an acceleration along the line joining the junctions, J_1, J_2, are in opposite directions in the two limbs of the device which carry opposite charges and which differ in potential by φ_c, the contact potential In this case,

$$\oint E\,.\,\mathrm{d}l \doteqdot \varphi_c\,\frac{h}{c^2}\,|a|$$

Because the field is non-conservative, it cannot be cancelled by a simple rearrangement of the surface charges If the principle of equivalence is valid, the same results as are obtained for an accelerated apparatus should apply to a similar system supported vertically in a gravitational field

If φ_c is about 1 V then $\varphi_c\frac{gh}{c^2} \sim 10^{-18}\,h$ V where h is in cm

The measurement of such a small voltage is technically feasible by using superconducting limbs of low inductance and the SQUID, a measuring device based on the Josephson effect[4].

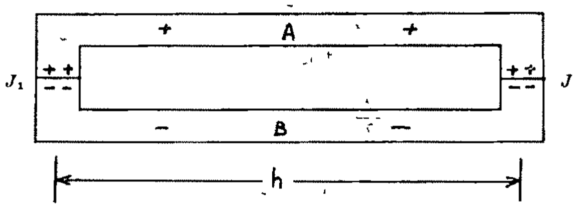

Fig 1 A shell made of two dissimilar metals There will be a contact potential across junctions J_1 and J_2

Witteborn and Pallesen[5] have used different experimental techniques which yielded an upper limit to any gravitational shift in contact potential of $\pm 10^{-9}$ V/m

Effect of Pipe Diameter, Vibration Amplitude, and Fluid Viscosity on Pipe Flow

IN view of the comments made by Silberman[1] on the communication by James and myself[2], I should like to draw attention to other experimental work that I have carried out to determine the effect of fluid viscosity, pipe diameter and amplitude of vibration on the flow of a fluid in a pipe Although at this stage the work does not cover as wide a range of significant variables as would be required for a complete investigation of the effect of vibrations in pipe flow, it does give an indication of the magnitude of the effects which are likely to be obtained for the conditions which were described by Silberman

This communication describes results obtained from two types of experiment, one of which was basically similar to that described by James and myself[2] This consists of determining the friction factor λ for a pipe where the static pressure tappings are situated 24 in apart and there is an entry length of 12 in The whole of the pipe was connected to an aluminium channel and vibrated in a plane perpendicular to the flow of fluid in the pipe by means of a slotted bar mechanism which was driven by a constant speed motor The pipe was free at its ends and tended therefore to bend and twist slightly when vibrating It was not flexibly mounted as in the previous experiments because it is believed that the mountings subject the pipe to conditions of shock The results of tests using this experimental arrangement are referred to as test *L*

In the other experiment, to be referred to as test *S*, a 12 in length of pipe, midway between two static pressure tappings which were 24 in apart, was attached to a 12 in length of aluminium channel and vibrated as described here Each static pressure tapping and a 2 5 in length adjacent to it on the vibrated side was rigidly clamped to a frame so that it was kept stationary The inlet length of 12 in and the pipe downstream of the test section was also clamped to the frame

The results of experiments, which were carried out on a pipe of diameter 0 164 in which was vibrated according to test *L*, are shown in Fig 1, where the effect of the amplitude of vibration and viscosity on the friction factor can be seen as a function of Reynolds number, Re The test fluids were water and an oil A which had a kinematic viscosity approximately four times that of water

The effect of amplitude of vibration and viscosity is also shown in Fig 2 where a pipe, 0 0714 in in diameter, was vibrated according to test *S* The test fluids in this case were water and an oil B which had a kinematic viscosity approximately 1 4 times that of water The results are essentially the same as those obtained for a pipe of 0 0714 in diameter which was vibrated according to test *L*.

Figs 1 and 2 both show that for similar amplitudes of vibration, a reduction in kinematic viscosity increases the magnitude of the friction factor at a particular

Reynolds number. Furthermore, for a particular fluid at a fixed Reynolds number an increase in the amplitude of vibration increases the friction factor. The shape of the λ–Re curve is interesting because it shows that at certain vibration amplitudes the effect of increasing the friction factor extends down to a Reynolds number of 800 and lower, whereas in other tests and those shown for oil B in Fig. 2 the curves in the turbulent region for vibrating and non-vibrating conditions are similar.

It is noticeable from Figs. 1 and 2 where all the tests were carried out at a frequency of 25 c/s that there is a diameter effect present because the curves of λ–Re for amplitudes of 0.175 in. and 0.37 in. for water are much closer together in the 0.164 in. diameter pipe than they would have been in the 0.0714 in. diameter pipe.

Fig. 3

It is interesting to note that the curves for λ–Re are similar to those obtained by White[3] for flow through curved pipes. The streamline motion of a fluid in a curved pipe was analysed theoretically by Dean[4,5], who showed the significance of the function $\frac{1}{2}\mathrm{Re}\left(\frac{r}{R}\right)^{\frac{1}{2}}$ (now known as the Dean number) to this type of flow. In the function r is the radius of the pipe and R is the radius of the bend.

It would seem that when a fluid flows along a pipe which is being vibrated in a direction perpendicular to the flow, as a particle of fluid moves along the pipe, it seems to flow through a series of bends. Suppose that the pipe is being vibrated with an amplitude A and a frequency n. If the mean velocity of flow in the pipe is u, then a particle of fluid will have moved a distance $u/4n$ along the pipe while the pipe moves a distance A perpendicular to the flow direction. To a first approximation the radius of curvature of the bend (assumed to be of a circular form) is given by R where

$$R=(u^2+16A^2n^2)/32An^2$$

The flow through such a pipe is more likely to depend on A/R than on r/R, except when A/r is very small. Thus the Dean number can be modified to

$$D_m=\frac{1}{2}\ \mathrm{Re}\ (A/R)^{\frac{1}{2}}$$

Substituting for R and putting $\mathrm{Re}=2ur/v$ where v is the kinematic viscosity

$$D_m=\mathrm{Re}\sqrt{x^2/2(1+x^2)}$$

for $x=\frac{4}{\mathrm{Re}}\left(\frac{And}{v}\right)$ and $d=2r$.

In order to determine the effect of vibration on friction factor, experimental values of λ/λ_0, where λ_0 is the friction factor for the unvibrated pipe, are plotted in Fig. 3 against the modified Dean number as curve *AB*. This curve is represented by the relationship

$$\frac{\lambda}{\lambda_0}=0.33\ D_m^{0.20}$$

For values of $x>1.0$ the flow path has a minimum radius of curvature which is smaller than that obtained by using the formula which was mentioned earlier. The magnitude of the effect depends on whether x is being increased by varying the term n/u or the amplitude A. At Reynolds numbers of 2,000, 1,500 and 1,000 the respective values of Dean number for $x = 1{\cdot}0$ are 1,000, 750 and 500. Where $x < 1{\cdot}0$, the friction factor equation given here fits the experimental points quite well, but the points showing most scatter are in general those where $x > 1{\cdot}0$.

The effect of the shape of the displacement time curve is another factor among others which could well influence such an expression because results which were obtained where the pipe was subject to shock conditions lay above the general shape of the curve AB at the points S. These results (curve DC) were obtained using the experimental arrangement described by James and myself[2] where the tests were carried out on pipes having test lengths of 4 in. and 24 in.

The oscillations which were set up by the flow round a bend were analysed by Hawthorne[6] in the case of a non-viscid fluid; this could also be an important factor which influences the flow of a fluid through a vibrating pipe which seems to be sinuous in form to a particle.

With a pipe rigidly fixed at each end and vibrated at the centre as described by Silberman it is not likely that the results would be much different (subject to the comment expressed later) to those expected from the above relationship.

Values of Adn/v and a modified Dean number are tabulated in Table 1 for a range of the most significant vibrating conditions referred to by Silberman.

Table 1

Frequency (c/s)	Amplitude (in.)	Loops	$\frac{Adn}{v}$	D_m Re = 2,000	D_m Re = 1,000
Magnetic vibration					
23·3	0·188	1	47	132	131
46·7	0·125	3	62	175	171
93·3	0·093	3	92	256	244
187	0·063	5	125	343	316
Hydraulic vibration					
31·7	0·250	1	84	233	232

It can be seen from Fig. 3 that in the tests which were carried out by Silberman using an oil of kinematic viscosity $2{\cdot}4 \times 10^{-4}$ ft.^{2}/sec, the effect is likely to be small. The amplitude referred to in Table 1, however, presumably refers to that of the vibrator at the centre of the pipe. For one loop, only the centre of the pipe will have this amplitude, the rest of the pipe being subject to vibrations where the amplitude reduces to zero at the clamps. This would suggest that the amplitude of vibration which is equivalent to the tests on which the formula is based should be reduced. Furthermore, with such a small change in the friction factor, this effect coupled with an additional 28 in. of non-vibrated pipe outside the clamps, yet between the static pressure tappings, could reduce the effect to an unmeasurable quantity. Similar reasoning could be applied to the cases of three and five loops where the amplitude in the loops not connected to the vibrator could also be less.

It is interesting to note that Silberman refers to a series of tests on water where at Reynolds numbers above 2,200 the flow could be turned from laminar to turbulent with certain types of vibration. Calculations based on the formula here indicate that, for water, very definite changes would be expected in friction factor for the vibrations mentioned in Table 1 if the pipe had been vibrated as a whole.

Possible Systematic Error in the Measurement of Normal Stress Differences in Polymer Solutions in Steady Shear Flow

It is well known[1] that, in suitable flow conditions, the normal stress differences $p_{11} - p_{22}$ and $p_{22} - p_{33}$ are determined by the values of pressure, $-p_{22}$, on the stationary and rotating walls of cone and plate (cp), plate and plate (pp) and concentric cylinder (cc) apparatuses. The common use of small holes (filled with static liquid) for measuring these pressures must give rise to a systematic error, p_{H} say, where

$$p = p_{\mathrm{H}} - p_{22} \tag{1}$$

is the pressure recorded using a hole and $-p_{22}$ is the pressure which would act on the wall if the hole were absent.

In spite of a warning by Schultz-Grünow[2], p_{H} has hitherto been neglected in the analysis of polymer solution data, partly because Greensmith and Rivlin[3] found that holes of diameters 1·0, 1·7 and 2·6 mm gave indistinguishable results, and partly because estimates for Newtonian liquids suggest that p_{H} will be small[4] (p_{H} about $0{\cdot}05\, p_{21}$, where p_{21} denotes the value of shear stress near to but unperturbed by the hole).

Some recent measurements, however, lead us to suggest that polymer solutions generate much higher values of p_{H} (p_{H} about $2\, p_{21}$) and that, when the $p_{\mathrm{H}}-$ contribution is taken into account, it will be possible to resolve certain known disagreements[5] between the results of measuring normal stress differences in different ways.

If we assume (*a*) that p_{H} is determined by p_{21}, and (*b*) that p_{H} is independent of the gap between the walls, then the equation[1]

$$\Delta_{cp} \equiv -\left(r\frac{\mathrm{d}p}{\mathrm{d}r}\right)_{cp} = p_{11} + p_{22} - 2\, p_{33} \tag{2}$$

for the pressure gradient in the cone and plate apparatus is unaltered, but the equation for the rim pressure $p(R)$ becomes

$$p(R) = p_{33} - p_{22} + p_{\mathrm{H}} + p\mathrm{a} \tag{3}$$

where pa denotes atmospheric pressure, R denotes the radius of the rotating member, and r denotes distance from the axis of rotation. The equations[1] for the plate and plate and concentric cylinder systems become

$$\Delta_{pp} \equiv -\left(r\frac{\mathrm{d}p}{\mathrm{d}r}\right)_{pp} = p_{11} - p_{33} + G\frac{\mathrm{d}}{\mathrm{d}G}(p_{22} - p_{33}) - \left(G\frac{\mathrm{d}p_{\mathrm{H}}}{\mathrm{d}G}\right)_{pp} \tag{4}$$

$$\Delta_{cc} \equiv -\left(r\frac{\mathrm{d}p}{\mathrm{d}r}\right)_{cc} = p_{11} - p_{22} + 2\left(p_{21}\frac{\mathrm{d}p_{\mathrm{H}}}{\mathrm{d}p_{21}}\right)_{cc} \tag{5}$$

G denotes the value of shear rate.

Using the apparatus of Adams and Lodge[5], with the hole diameters increased to 1·3 mm, we find that, for a 2 per cent solution of a high molecular weight polyisobutene ('Oppanol *B*200') in a low molecular weight liquid polyisobutene ('Oppanol *B*1'), Δ_{cp} is independent of r, consistent with equation (2). This is our reason for assumption (*b*). We also find that $p_{11} - p_{22}$, determined from values of the total thrust, F, in a second cone and plate apparatus[6] (which uses no holes for pressure measurement) according to the equation[1]

$$p_{11} - p_{22} = \frac{2F}{\pi R^2} \tag{6}$$

is equal to $2\, p_{21} \cot 2\chi$, where χ denotes the flow birefringence extinction angle measured in the concentric cylinder apparatus of Kaye and Saunders[7]. Values of p_{21} measured in the two latter apparatuses agree with one another.

It is therefore tempting to suppose that our data for Δ_{cp} and F do give correct values for $p_{11}-p_{22}$ and $p_{22}-p_{33}$ by means of equations (2) and (6); we find that, in the range $5<G<25$ (units, sec^{-1}),

$$p_{11} - p_{22} = 240\,G + 500 \qquad (7)$$

$$0 < p_{33} - p_{22} < 0{\cdot}07\,(p_{11} - p_{22}) \qquad (8)$$

With these values for $p_{11}-p_{22}$ and $p_{22}-p_{33}$ and measured values of $p(R)$, we may now calculate the value of p_{H}, using equation (3); we find that, in the range $200<p_{21}<500$,

$$p_{\mathrm{H}} = -3{\cdot}07\,p_{21} + 414 \qquad (9)$$

(units, dynes cm^{-2}).

Thus the holes generate a negative pressure greater in magnitude than the shear stress caused by the primary shear flow.

We can now test the validity of this procedure by using the above values of p_{H}, $p_{11}-p_{22}$ and $p_{22}-p_{33}$ to evaluate the right hand side of equation (4) and comparing the result with values of Δ_{pp} measured in the apparatus of Adams and Lodge. We find that equation (4) is satisfied within the accuracy of measurement, and that the contribution from the term involving p_{H} is substantial. In this way, a disagreement of the type noted by Adams and Lodge[5] (between equations (2), (3) and (4), with $p_{\mathrm{H}}=0$) is resolved.

A further test is afforded by equation (5) which, with equations (6) and (9), implies that

$$\Delta_{cc} < 2F/(\pi R^2) \qquad (10)$$

Our values for Δ_{cc}, obtained from a new concentric cylinder apparatus (J. M. Broadbent and A. S. Lodge, in preparation), with pressure-measuring holes of diameters 3 mm and 6 mm, are consistent with this inequality. Moreover, we find that in certain circumstances negative values are obtained for the pressure on the inner cylinder (even when the appropriate inertial force corrections have been made for the rotation of liquid in the gap and in the inner cylinder); similar results have recently been reported for an aqueous detergent solution[8]. These could be explained by a dominant negative value for p_{H}.

It is possible that, for certain tests of the validity of methods of determining normal stress differences, the contributions from p_{H} in different apparatus might partially cancel one another. For example, for the test obtained by elimination of $p_{11}-p_{22}$ and $p_{22}-p_{33}$ between equations (2), (4) and (5), we see that

$$\Delta_{pp} - \Delta_{cp} + \tfrac{1}{2}\left(G\frac{\mathrm{d}}{\mathrm{d}G} - 1\right)(\Delta_{cc} - \Delta_{cp})$$
$$= \left(G\frac{\mathrm{d}}{\mathrm{d}G} - 1\right)\left(p_{21}\frac{\mathrm{d}p_{\mathrm{H}}}{\mathrm{d}p_{21}}\right)_{cc} - \left(G\frac{\mathrm{d}p_{\mathrm{H}}}{\mathrm{d}G}\right)_{pp} \qquad (11)$$

In this way, it might be possible to explain Markovitz's result[9] that the left hand side of this equation is small for a 5·4 per cent solution of polyisobutene ('*B*100') in cetane, if the liquid properties and hole sizes were such that the right hand side was small.

If assumption (*b*) is valid, and if the constitutive equations for the liquid involve no material constants of the dimension of length, then dimensional considerations[5] suggest that p_{H} will not depend on the hole diameter, because there is no other quantity to form a dimensionless group with this. This rather surprising suggestion might explain the result of Greensmith and Rivlin[3], and suggests that changing the hole diameter might not be a sufficient test for the absence of a pressure contribution from the hole.

We acknowledge a grant from the Science Research Council, the gift of the concentric cylinder pressure measuring apparatus from Ferranti, Ltd., Moston, and gifts of polyisobutene ('Oppanol') from Badische Anilin und Soda Fabrik, Ludwigshafen am Rhein, Germany.

THE SOLID STATE

Epitaxy as a Growth Factor in Urinary Calculi and Gallstones

Epitaxy[1] consists of the growth of one crystal, in one or more particular orientations, on a substrate of another, with a near geometrical fit between the respective networks which are in contact. Thus anthraquinone can grow on rocksalt[2] and *d*- or *l*-camphor on *d*- or *l*-quartz[3]. That there is some influence of the structures themselves (apart from the geometry) has been proved, but it is of surprisingly minor importance[3]. There is also a dependence of the degree of misfit which can be tolerated on the degree of supersaturation of the solution from which the epitaxial crystals are deposited[4].

One curious feature of many kidney and bladder stones is the relatively abrupt change of composition which can occur from time to time during growth. Often there are alternating layers of differing composition around a nucleus, combined with a radial arrangement of the crystals[5] in the successive layers (Fig. 1).

Examination of the usual habits of crystals of the common stone-forming compounds (Table 1), together with the dimensions of the networks in the occurring faces, indicates that epitaxy may be of considerable importance in causing the stone to grow larger, once a suitable seed has been deposited. Without any such seed, the urine

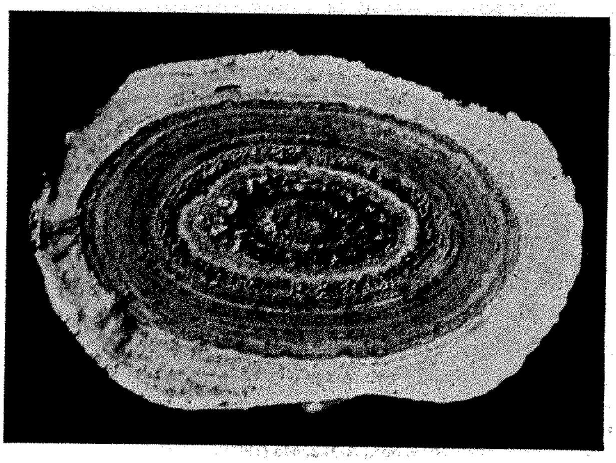

Fig. 1. A bladder stone showing the alternating layers of different composition around a nucleus. The relatively abrupt changes of composition during growth can be seen clearly.

Note: Ammonium acid urate, sodium acid urate and xanthine are not included because neither their habits nor their unit-cell dimensions are known. Ammonium acid urate does, however, sometimes give a slightly orientated powder pattern, with its 3·43 Å spacing either equatorial or meridional when the radial direction of a stone sample is set vertical in a Unicam X-ray photogoniometer. Xanthine also sometimes shows a tendency towards orientated overgrowth.

Newberyte, $MgHPO_4.3H_2O$, although of common occurrence on the surface or exposed sections of old stones, is not included because it appears to be a decomposition product of struvite, and therefore is not a primary component.

can attain a very high degree of supersaturation of certain relatively insoluble components without any deposition[6]. Deposition from a saturated or supersaturated solution of a stone-forming compound will occur at once on a suitable seed or substrate provided that there is an epitaxial relationship. Deposition might be prevented, however, either by habit-modification (provided that a suitable non-toxic additive could be found) or by a sufficient modification of network size, for example, by the substitution for part of the calcium of another divalent ion of different effective radius. Magnesium is the obvious choice (average distance Mg—O is 2·10 Å as compared with 2·40 Å for Ca—O) as long as it does not stimulate the production of struvite. If growth can be prevented, the chance of natural elimination of seed crystals is greatly increased.

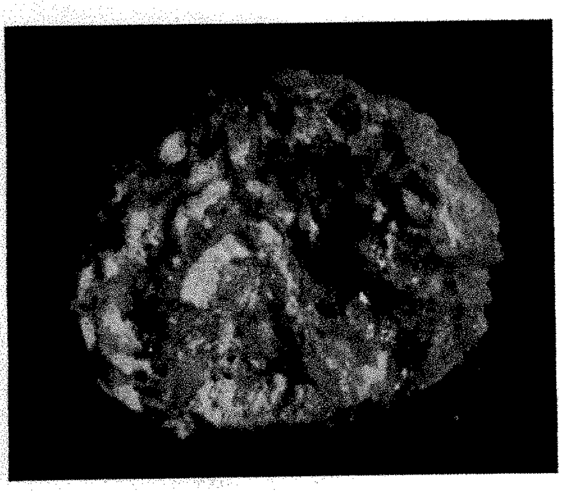

Fig. 2. The interior of a kidney stone, consisting of an intimate mixture of weddellite and apatite.

It is clear from Table 2 that a variety of excellent fits (too many to be purely coincidental) are possible for epitaxial growth on a nucleus of uric acid, uric acid dihydrate, whewellite or weddellite (in any order). These are the substances most frequently found in nuclei of adult urinary calculi. The phosphates more often occur in the outer layers, but frequently stones are found without any apparent nucleus; they seem to consist simply of agglomerations of crystals, some in very finely divided form. Thus Fig. 2 shows the interior of a kidney stone from a 4 year old boy; this consists of an intimate mixture of weddellite and apatite. The (101) network of weddellite and the (0001) network of apatite differ in linear dimensions by only 2·0 and 3·9 per cent. Each presumably can act as substrate for the other.

The role of any complex organic components in the growth of stones is not easy to define. It may be that they take part in the epitaxy, or they may act as a cementing material where epitaxy has not occurred. Nor is it easy to test which kind of epitaxy does actually occur, although it can be shown by X-ray diffraction that there

Normally occurring crystal faces with (near-) orthogonal networks which could grow on one another (including alternatives) in some common components. Note that epitaxy can occur between $a \times b$ and $na' \times mb'$ if a, a' (and b, b') only differ by a few per cent.

is orientated crystal growth (ref. 5, and unpublished work in this laboratory) in striated or layered calculi. X-ray diffraction, however, cannot determine the nature of the interfaces between neighbouring crystallites. Experiments to determine relative orientations of calculus components are, however, being made, and we propose also to attempt the growth of artificial stones on suitable crystal substrates and then to find out whether growth can be prevented by substrate modification. Similar experiments in other laboratories would be welcomed.

Refractive Indices of Mixed Crystals of Phenazine and *N*-Oxyphenazine

REFRACTIVE indices have been measured for the complete range of mixed crystals of phenazine and *N*-oxyphenazine. These measurements, which were repeated several times for each batch of crystals, indicate the presence of a discontinuity in the series, extending from 8 to 30 mole per cent of *N*-oxyphenazine.

Crystals of phenazine ($C_{12}H_8N_2$) and *N*-oxyphenazine ($C_{12}H_8N_2O$) crystallize out of methyl ethyl ketone. The crystallographic data are as follows

$C_{12}H_8N_2$: $P2_1/a$, $Z=2$,
$a=13{\cdot}20(\pm 0{\cdot}005)$, $b=5{\cdot}05(\pm 0{\cdot}02)$, $c=7{\cdot}08(\pm 0{\cdot}005)$ Å,
$\beta=109{\cdot}2(\pm 0{\cdot}05)°$,
$D_x=1{\cdot}341$ g/cm^3 (using $N=6{\cdot}023\times 10^{23}$ mole^{-1}),

$C_{12}H_8N_2O$: $P2_1/a$, $Z=2$,
$a=14{\cdot}29(\pm 0{\cdot}01)$, $b=4{\cdot}60(\pm 0{\cdot}02)$, $c=7{\cdot}44(\pm 0{\cdot}005)$ Å,
$\beta=108{\cdot}8(\pm 0{\cdot}05)°$,
$D_x=1{\cdot}404$ g/cm^3

The cell dimensions were determined at room temperature (21° C) from Straumanis-loaded films with cobalt radiation, the calculations being done by least squares refinement on five to seven reflexions (λ K$\bar{\alpha}=1{\cdot}7902$ Å). The structures of these substances are known[1,2].

In the crystal structure of *N*-oxyphenazine, the molecules are arranged in a disordered manner, thus producing a statistical centre of symmetry. A similar situation occurs in anthrone[3].

Phenazine and *N*-oxyphenazine are reported[2] to form a continuous solid solution series. According to Kitaigorodskii[4], this would only be possible if overall symmetry were retained on substitution of foreign molecules in a "host" lattice. Some evidence for this has been provided by studies of several organic mixed crystal series, which were grown from the melt, for example, acridine–anthracene[5], anthracene-phenanthrene[6], dibenzyl-stilbene[7] and tolane–mercury diphenyl[8].

Phenazine and *N*-oxyphenazine easily produce flat, needle-like crystals with well developed (20Ī) faces from solution[2]. Because there is some inherent structural disorder in one end member (*N*-oxyphenazine) we felt that this would be an interesting system to study.

The crystals were grown from methyl ethyl ketone in sealed glass containers and the compositions were determined to ~1 per cent by ultraviolet spectroscopy (phenazine peak at 250 mμ, *N*-oxyphenazine peak at 266 mμ; in ethanol). This was necessary because the difference in solubility between the two components meant that the composition of the mixed crystals was not the same as that of the original mixed solute.

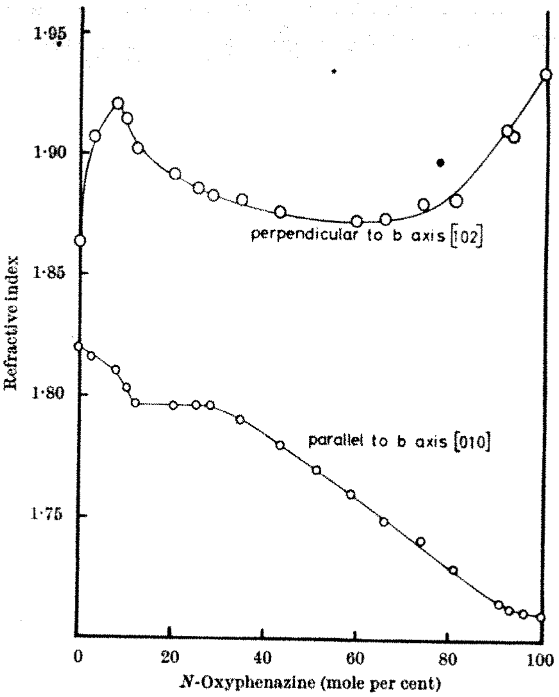

Fig. 1.

It was immediately noticed that crystals having a composition between 10 and 40 mole per cent *N*-oxyphenazine were fibrous and badly formed, the worst crop of crystals having a composition of 25 mole per cent. It therefore seemed possible that there was a region of immiscibility; that is that the system was one of partial miscibility and not a continuous solid solution series.

Attempts to construct a phase diagram were hampered by the thermal decomposition of *N*-oxyphenazine. A graph of cell dimensions against composition seemed to give a set of smooth curves, with a break only where the crystals were too poor for X-ray study. It was thought that an investigation of refractive index against composition might give evidence for or against a partially miscible system.

At first, a great deal of difficulty was encountered in measuring the high refractive indices (above 1·86) and immersion media in this region tended to attack and dissolve the crystals. Eventually it was found that suitable results could be obtained by using a mixture of arsenic tribromide, arsenic sulphide and arsenic triiodide[9,10]. This was a very stable mixture, giving refractive indices higher than 1·94. Using a Leitz–Jelley refractometer, with sodium light, measurements of up to 1·92 could be made, to an accuracy of ± 0·001. Methylene iodide was used to dilute the medium in order to vary the refractive index. Because solution of the crystals still occurred, observations of the Becke line were made as rapidly as possible. The effect of dissolved material on the refractive index liquid was a change of the order of 0·001. Measurements were made parallel and perpendicular to the *b* axis. In the case of phenazine, the refractive index along *b* was the β index and agreed with the literature value[11]. It was not possible to ascertain whether this was also true for *N*-oxyphenazine because a suitable interference figure could not be obtained. A graph of refractive index parallel and perpendicular to the b axis is plotted against composition in Fig 1 This shows that there is a remarkably large peak at a composition of 8 mole per cent of N-oxyphenazine for refractive indices which were measured perpendicular to the b axis [102], while measurements parallel to the b axis [010] show a depression starting at 8 mole per cent and ending at 30 mole per cent X-ray photographs showed that the crystals, at all compositions, had the same developed faces Thus the refractive index measurements perpendicular to the b axes were always obtained with the same crystal face perpendicular to the microscope axis

The exact reason for the two effects, however, is not yet apparent and an X-ray investigation of the series, at present in progress, may throw more light on the shapes of these curves

CHEMISTRY

Initiation of Free Radical Polymerization by Manganese Carbonyl and Carbon Tetrachloride

Initiation of free radical polymerization by metal carbonyls in the presence of organic halides has been shown, in all cases studied, to involve a rate determining primary activation of the carbonyl, in which the halide does not participate[1,2] In the system $Mn_2(CO)_{10}$ + CCl_4 + monomer, the monomer does not enter into this process[2], which would therefore seem likely to consist either of scission of carbon monoxide from the carbonyl molecule or rupture of the metal–metal bond After considering both possibilities, we concluded that experimental data from polymerization studies favour the former[2] Wawersik and Basolo reached a similar conclusion for substitution reactions of manganese carbonyl[3] On the other hand, Hopgood and Poe reported that substitution, oxidation and decomposition reactions of $Mn_2(CO)_{10}$ involve primary fission of the manganese–manganese bond[4], although more recently Haines and Poe have stated that carbon monoxide-scission contributes an additional rate determining step[5] Haines and Poe therefore propose[5] that in the initiation of polymerization both primary steps occur, giving rise to two independent mechanisms, A and B

$$(A) \qquad \mathrm{Mn_2(CO)_{10}} \underset{k_{-1}}{\overset{k_1}{\rightleftharpoons}} \{\mathrm{2Mn(CO)_5}\} \tag{1}$$

$$\{\mathrm{2Mn(CO)_5}\} + \mathrm{CCl_4} \xrightarrow{k_2} \mathrm{Mn(CO)_5Cl} + \mathrm{Mn(CO)_5} + \dot{\mathrm{C}}\mathrm{Cl_3} \tag{2}$$

$$\mathrm{Mn(CO)_5} + \mathrm{CCl_4} \xrightarrow{k_3} \mathrm{Mn(CO)_5Cl} + \dot{\mathrm{C}}\mathrm{Cl_3} \tag{3}$$

$$\mathrm{Mn(CO)_5} \xrightarrow{k_4} \text{inactive products} \tag{4}$$

$$(B) \qquad \mathrm{Mn_2(CO)_{10}} \underset{k_{-5}}{\overset{k_5}{\rightleftharpoons}} \mathrm{Mn_2(CO)_9} + \mathrm{CO} \tag{5}$$

$$\mathrm{Mn_2(CO)_9} + \mathrm{CCl_4} \xrightarrow{k_6} \dot{\mathrm{C}}\mathrm{Cl_3} + \text{inactive products} \tag{6}$$

$$\mathrm{Mn(CO)_9} \xrightarrow{k_7} \text{inactive products} \tag{7}$$

Unfortunately, these authors make an elementary error in their kinetic treatment by assuming that the rates of polymerization, corresponding to the separate mechanisms, are additive, and so arrive[5] at the incorrect rate expression (8) In this equation a, b are given by equations (9) and (10), ω is the rate of polymerization, M represents monomer and k_p, k_t are the velocity coefficients for chain propagation and termination, respectively

$$\omega = \omega_A + \omega_B = k_p k_t^{-\frac{1}{2}}[M]\,[\mathrm{Mn_2(CO)_{10}}]^{\frac{1}{2}}(a+b) \tag{8}$$

$$a = \left(1 + \frac{k_3[\mathrm{CCl_4}]}{k_4 + k_3[\mathrm{CCl_4}]}\right)^{\frac{1}{2}} \left(\frac{k_1 k_2[\mathrm{CCl_4}]}{k_{-1} + k_2[\mathrm{CCl_4}]}\right)^{\frac{1}{2}} \tag{9}$$

$$b = \left(\frac{k_5 k_6[\mathrm{CCl_4}]}{k_{-5}[\mathrm{CO}] + k_7 + k_6[\mathrm{CCl_4}]}\right)^{\frac{1}{2}} \tag{10}$$

The correct rate expression, based on the additivity of rates of initiation, is given in equation (11)

$$\omega = k_p k_t^{-\frac{1}{2}}[M][\mathrm{Mn_2(CO)_{10}}]^{\frac{1}{2}}(a^2+b^2)^{\frac{1}{2}} \tag{11}$$

The validity of Haines and Poe's claim that their mechanism is in excellent quantitative agreement with our experimental data is called in question by these considerations In specified conditions[5], the rate of initiation predicted by equations (1) to (7) with their parameters is only 57 per cent of that measured by us[2], while equation (8) suggests rather precise agreement Perhaps more significant is the fact that the mechanism does not account satisfactorily for the behaviour of the system in the presence of added carbon monoxide It is easy to show from equation (11) that, at high $[\mathrm{CCl_4}]$,

$$\frac{\omega([\mathrm{CO}]=0)}{\omega([\mathrm{CO}]=\infty)} = \left(\frac{2k_1+k_5}{2k_1}\right)^{\frac{1}{2}} \tag{12}$$

so that, with the values of Haines and Poe for k_1, k_5, the ratio has the value 1 08, compared with the experimental figure[6] of 1 21 for a carbon monoxide pressure of 775 mm of mercury Fig 1 of Haines and Poe, in which they purport to demonstrate a sensitivity to carbon monoxide similar to that observed experimentally, is incorrect, because the calculated rate for $[\mathrm{CO}]=0$ is derived from equation (8) Furthermore, it seems to be assumed, with no obvious experimental justification, that a pressure of carbon monoxide of 760 mm of mercury is kinetically equivalent to $[\mathrm{CO}]=\infty$

Whether or not the mechanism of equations (1) to (7) may be modified to overcome these shortcomings is debatable, it is important to note that our measured rates of polymerization are initial values, and thus are not affected by reactions of intermediates with half-lives comparable with that of $Mn_2(CO)_{10}$ It is relevant to the postulation of $Mn(CO)_5$ radicals that in the polymerization of methyl methacrylate at 25° C photosensitized by $Mn_2(CO)_{10}+CCl_4$ the quantum yield for initiation is unity and unsymmetrical fission of the manganese–manganese bond has been postulated as the primary act[7]

Adsorption Efficiency in the Collision of Molecular Oxygen with Clean Tungsten Surfaces

Morrison and Roberts[1] obtained consistent calculations for the variation of the accommodation coefficient of neon on a tungsten filament during the adsorption of oxygen using the assumption that the sticking probability for oxygen on tungsten is initially unity and independent of coverage Later work on filaments and ribbons, using the sophisticated techniques of ultra-high vacuum technology and the more direct flash filament method for measuring sticking probabilities[2] has, however, produced values between 0 1 and 0 2 (refs 3 to 6), although Schlier[7] has reported a value of 0 65

The sticking probability can be obtained directly using a reflexion detector technique in which a detector (ionization gauge or mass spectrometer) is so placed relative to adsorbent and gas supply that gas molecules can only enter it after collision with the adsorbent The cell used in the present work is diagrammatically illustrated in Fig 1, and is a modification of a previous design[8,9] Using modern ultra-high vacuum techniques[10], vacua of about 2×10^{-11} torr (nitrogen equivalent, measured by a Redhead modulated Bayard-Alpert ionization gauge[11] with a thoria-coated filament) were achieved in the cell The adsorbent was obtained by depositing metal vapour from a thoroughly outgassed tungsten wire (0 3 mm diameter, Murex Ltd, grade 1) on to the walls of the 1 litre spherical reaction cell Oxygen gas was directed at the film from a centrally positioned retractable diffuser, and the gauge side-arm designed so that gas from the diffuser could not enter the gauge tubulation without first colliding with the metal film Because even low concentrations of non-adsorbable impurities from the gas supply accumulate in the cell, giving an anomalous pressure reading and thus a low apparent sticking probability[8], great care was taken in the preparation of impurity-free oxygen by heating very thoroughly outgassed potassium permanganate British Oxygen Company bottled oxygen was found to be unsuitable It is necessary to use a modulated ionization gauge to measure oxygen pressure because, as shown by Redhead[11] and Singleton[12] and confirmed in our work (results to be published), the residual pressure varies with the amount of exposure of the gauge to oxygen To reduce the effect of pumping by the gauge, it was "saturated" with oxygen, at a pressure of about 10^{-7} torr, after outgassing and before film deposition The sticking probability s can be evaluated from the simple relationship

$$s=\frac{\text{rate of adsorption}}{\text{rate of bombardment}}=\frac{r_i}{r_i+\text{reflexion rate}}$$
$$=1/(1+ZP/r_i) \qquad (1)$$

where Z is the Knudsen collision factor, P the gauge pressure reading and r_i the rate of gas inflow into the cell

With the cell maintained at 78°, 195° or 300° K, when the gas supply was first opened ($r_i=6\times10^{11}$ molecules sec^{-1} cm^{-2} geometric area of film) to a clean film the pressure rise was $<1\times10^{-11}$ torr, from equation (1), this indicates an initial sticking probability s_0 within the limits

$$1\geq s_0>0\ 997$$

Furthermore, after adsorption for about 20 min the gauge pressure had only risen by 8×10^{-11} torr at 195 or 300° K, while at 78° K no rise was observed, the initial sticking probability is therefore very close to unity and is virtually independent of coverage up to at least 10×10^{14} molecules/cm^2 geometric area of film These results therefore confirm the original self-consistent assumptions made by Morrison and Roberts[1] but apparently contradict the more recent flash filament results

It is not possible to attribute the discrepancy to differences in either gas or surface temperatures The possibility that differences may be attributable to differences in the nature of the adsorbent surfaces should be considered (1) Metal films are porous and present a rough surface to the impinging gas molecules, resulting in multiple collisions (as discussed in detail elsewhere[13]) while filaments possess relatively low roughness factors But $s=1$ for a rough surface requires that s is also unity for a perfectly smooth surface (2) The exposed crystal planes in tungsten film and filament surfaces may occupy different fractional areas The value of unity for s, however, implies that all planes exposed in the film are capable of adsorbing oxygen with $s=1$, it is most unlikely that planes exposed in filaments are not present in the

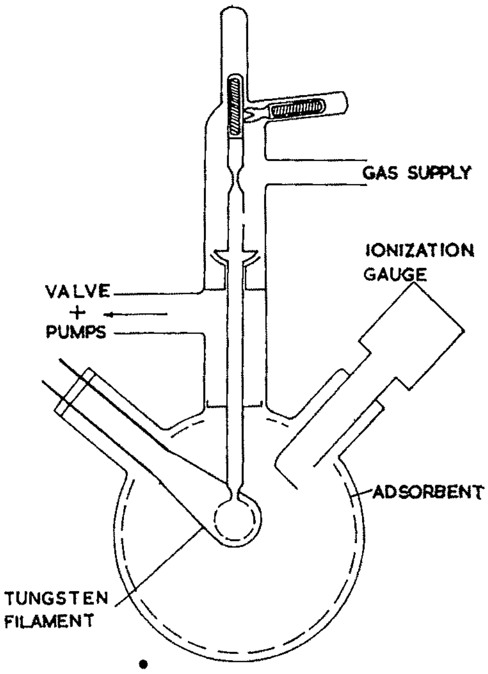

Fig 1 The adsorption cell ('Pyrex' glass)

polycrystalline films Thus the discrepancy seems to be caused by an experimental artefact in the flash filament technique for the oxygen-tungsten system

Reflexion detector techniques (rdt) possess a number of advantages over flash filament techniques (fft) As $s \to 1$, $P \to 0$ in equation (1) and the calculated value of s becomes virtually independent of the gauge calibration factor with rdt, while it is a critical factor with fft With rdt, by operating at low adsorption rates the experiment can be made to last hours, while with fft experiments are usually over in seconds, with a concomitant loss of detail and accuracy. With rdt the gauge can be operated intermittently, thereby reducing the possibility of gauge phenomena affecting the results, while with fft gauge effects are magnified because the area of the adsorbent is approximately equal to that of the gauge grid (usually molybdenum), and the gauge must be operated continuously Finally, with fft adsorption rates are measured from the pressure drop occurring when the filament is cooled, and reversible desorption from the gauge grid would result in an anomalously small pressure drop, and thus an anomalously low calculated value for the sticking probability

Huckel Molecular Orbital Models for Heterocycles with Tetra-coordinated Phosphorus Atoms

MANY heterocyclic compounds with tetra-coordinated phosphorus atoms have been synthesized[1,2]. Several models for Huckel molecular orbital calculations[3–6] have been proposed for heterocycles containing atoms with *d*-orbitals, but the most suitable model should first be found before such calculations are made for these phosphorus heterocycles The most suitable model can be found by comparing the experimental data for phosphabenzene (more exactly 1,1-diphenylphosphabenzene)[1,7,8] with the Huckel parameters calculated for all these models

Three models could be used for Huckel molecular orbital calculations in tetra-coordinated pentavalent phosphorus heterocycles. Fukui *et al.*[3] considered one normal $d\pi$ orbital (a d^3s hybrid) and one π electron for the phosphorus atom. According to Mason[4] and Craig and Paddock[5], the $d\pi$ orbital of the phosphorus atom should be a $3d_{xy}$ orbital, which yields β exchange energy integrals differing in sign from the two adjacent $2p\pi$ carbon orbitals. According to Dewar[6], the phosphorus atom should have two orthogonal $3d\pi$ orbitals, conjugation being interrupted at the phosphorus atom We used four models in our Huckel molecular orbital calculations of formally unsubstituted phosphabenzene (1) the normal Fukui model with $\alpha_P = \alpha - 0{\cdot}6\beta$, $\beta_{CP} = 0{\cdot}9\beta$, (2) the "anti-Huckel" model of Mason and Craig with $\alpha_P = \alpha - 0{\cdot}6\beta$, $\beta_{CP} = 0{\cdot}9\beta$, $\beta_{C'P} = -0{\cdot}9\beta$, (3) the Dewar model, with 7 atomic orbitals $\alpha_P = \alpha_{P'} = \alpha - 0{\cdot}6\beta$, $\beta_{CP} = \beta_{C'P'} = 0{\cdot}9\beta$, $\beta_{PP'} = 0$, and (4) the weak phosphorus–carbon interaction model (normal Fukui model) with $\alpha_P = \alpha - 3\beta$, $\beta_{PC} = 0{\cdot}3\beta$ The α_P parameter was chosen so that the $3d\pi$ phosphorus orbital was slightly more electronegative than the $3p\pi$ phosphorus orbital, for which Pauling electronegativity considerations (work to be published) indicated that $\alpha_P = \alpha - 0{\cdot}4\beta$ The phosphorus parameters for weak phosphorus–carbon interaction are those of Brown and McCormack[9] The results are listed in Table 1

Table 1. HÜCKEL MOLECULAR ORBITAL CALCULATIONS FOR PHOSPHABENZENE

Σ_{LE}	$\alpha - 1{\cdot}000\beta$	$\alpha - 0{\cdot}222\beta$	$\alpha - 0{\cdot}317\beta$	$\alpha - 1{\cdot}000\beta$
Σ_{HO}	$\alpha + 0{\cdot}727\beta$	α	$\alpha + 0{\cdot}483\beta$	$\alpha + 0{\cdot}040\beta$
R	$1{\cdot}916\beta$	$1{\cdot}098\beta$	$1{\cdot}752\beta$	$1{\cdot}496\beta$
q_1	0·687	0·410	0·892	0·029
$q_2 = q_6$	1·074	1·384	1·168	1·324
$q_3 = q_5$	1·016	0·784	0·834	1·000
q_4	1·142	1·333	1·070	1·324

According to model (1), phosphabenzene should be a stable aromatic heterocycle The first ultraviolet band should be somewhat displaced towards the red in comparison with benzene, for 1,1-diphenylphosphabenzene $\Sigma_{LE} - \Sigma_{HO} = -1{\cdot}376\beta$ and with the usual spectroscopic $\beta = -2{\cdot}5 \times 10^4$ cm^{-1} the first absorption maxima should be at 2900 Å. According to model (2), phosphabenzene should be unstable towards both electron accepting and electron donating reactions, towards radical reactions (dimerizations) or should be, in fact, biradical (small $\Sigma_{LE} - \Sigma_{HO}$ differences) The electronic spectrum should be at very long wavelengths According to model (3), phosphabenzene should be stable The first absorption maxima (calculated with $\beta = -2{\cdot}5 \times 10^4$ cm^{-1}) should be at about 5000 Å According to model (4), phosphabenzene should behave similarly to the $R(\mathrm{CH})_5R^-$ anion It should be an amphiionic substance with a basicity similar to the

$$(\mathrm{CH_3})_3\mathrm{N^+}\text{—}\mathrm{CH^-}\text{—}\mathrm{CH{=}CH_2} \overset{\pm\mathrm{H}^+}{\rightleftharpoons} (\mathrm{CH_3})_3\mathrm{N^+}\text{—}\mathrm{CH_2}\text{—}\mathrm{CH{=}CH_2}$$

equilibrium As shown in the *Beilstein's Encyclopaedia*[10], the quaternary ammonium hydroxide with allyl substituents is a strong base and does not show a tendency to deprotonate in aqueous media

1,1-Diphenylphosphabenzene is obtained as a yellow precipitate from aqueous solutions with an electronic maxima at 4090 Å in aetheric solution The substance is stable in water but is protonated in position 2 in acidic solutions It is extremely prone to auto-oxidation[1,7,8]

The electronic spectra and the general stability eliminate the "anti-Huckel" model (2) Auto-oxidability is a general tendency of organic phosphorus compounds and does not seem to be caused by peculiarities of the π electronic system. The moderate basicity eliminates model (4) based on the weak phosphorus–carbon interaction There remain the normal Fukui model (1) and the Dewar model (3); to decide between them, more comparisons between the Huckel calculations and the experimental data for tetracovalent phosphorus-heterocycles are necessary

BIOCHEMISTRY

Comparison of the Kinetics of Photosynthetic Carbon Dioxide Fixation in Maize, Sugar Cane and Tobacco, and its Relation to Photorespiration

Most plants exhibit the phenomenon of photorespiration that is to say they give out a certain amount of carbon dioxide in the light This effect is usually masked by the occurrence of photosynthesis which takes up carbon dioxide at a greater rate than photorespiration releases it Photorespiration can, however, usually be demonstrated by allowing leaves to photosynthesize in an enclosed space when they are unable to reduce the carbon dioxide concentration of the atmosphere below about 50–100 p p m This is because at this point carbon dioxide starvation reduces the rate of photosynthesis to a level at which it equals photorespiration and therefore no further net uptake of carbon dioxide is observed More recently, a small group of plants, including maize and sugar cane, has been investigated, which can reduce the carbon dioxide concentration of a closed system virtually to zero[1] This could be the result either of their having a poor photorespiratory mechanism or of their possessing an unusually efficient photosynthetic mechanism There is evidence that the mechanism of photosynthetic carboxylation at least is different in maize and sugar cane from that in most other plants, for the initial product of photosynthetic carbon dioxide fixation in maize and sugar cane is oxalo-acetate, rather than the phosphoglycerate which is the normal product of most plants[2] Thus if different carbon dioxide fixing enzymes were operating in maize and sugar cane, this could well account for an increased affinity for carbon dioxide in these species

To test this, the apparent Michaelis constants for photosynthesis of maize and sugar cane were determined and compared with that of tobacco, which exhibits normal photorespiration[3] and normal photosynthesis with phosphoglycerate as initial product[2] The apparent Michaelis constant is the external carbon dioxide concentration which enables the leaf, at saturating light intensity, to fix carbon dioxide at half the maximal velocity While it is not claimed that this represents the true Michaelis constant for the photosynthetic carboxylating enzyme, it does, by analogy, represent the affinity of the overall photosynthetic system for carbon dioxide—the lower the apparent Michaelis constant the greater being that affinity In order to eliminate the effect of photorespiration on measurements of photosynthesis, photorespiration was suppressed by measuring the uptake of carbon dioxide in an atmosphere of nitrogen This suppression can be clearly shown by the fact that in these conditions a photosynthesizing tobacco leaf segment can reduce the concentration of carbon dioxide in the atmosphere almost to zero

The technique for determining the apparent Michaelis constants for the tissues examined was as follows The apparatus consisted of a 'Perspex' leaf chamber submerged 10 cm beneath the surface of a water bath at 20° C One to five leaf segments, cut to a total area of 100 cm², so as to exclude the main veins, were floated, undersurface upwards, on 20 ml of distilled water in the leaf chamber and illuminated from above at 6,000 ft -candles from a tungsten source A gas stream was pumped from the leaf chamber through a magnesium perchlorate drying tower to an infrared carbon dioxide analyser and then returned to the chamber so as to complete the circuit The rate of gas flow was approximately one circuit/min The leaves were illuminated in air for at least 1 h before measurements were commenced The system was then charged with gas by flushing it with 6,000 p p m carbon dioxide in nitrogen, the circuit sealed off and the concentration of carbon dioxide plotted against time The relative rate of fixation at any particular concentration of carbon dioxide was measured as the slope of a tangent drawn to the curve at that concentration

Table 1

	First replicate		Second replicate		Third replicate	
Species	Max rate	*Km*	Max rate	*Km*	Max rate	*Km*
Tobacco	500	330	520	330	450	290
Sugar cane	400	300	440	330	380	270
Maize	250	260	380	270	330	325

Km (apparent Michaelis constant) is expressed as p p m carbon dioxide

Maximum rate is expressed as p p m reduction in the carbon dioxide concentration in the circuit/min In all cases the rate of fixation was constant at all concentrations of carbon dioxide tested above 1,000 p p m

Table 1 shows that the apparent Michaelis constants for the photosynthesis of all three species are similar, the value being approximately equal to the natural carbon dioxide concentration of the Earth's atmosphere This finding indicates that the affinity for carbon dioxide of these three species is not greatly different It may therefore be argued that the apparent lack of photorespiration in maize and sugar cane is the result of a true deficiency in this process rather than the possession of an unusually efficient photosynthetic mechanism

Effect of Kinetin on the Phosphatase Enzymes of *Acetabularia*

The effect of auxins on higher plants has been extensively studied[1–3] but their action on algae is not clear Thimann and Beth[4] concluded that while various auxins promoted some aspects of algal growth, there was a wide variation in the effect and the specificity of action was uncertain They also measured the effect of indole acetic acid and naphthalene acetic acid on the growth of nucleate and enucleate *Acetabularia mediterranea* They found that these auxins increased the growth rate but did not affect cap formation in mature cells Similar effects occurred to a smaller extent in enucleate cells

Brachet[5] has reported that kinetin inhibits the growth of *Acetabularia* at 4 6 × 10^{-9} molar, but later de Vitry[6] found an increased growth rate at the same concentration Zetsche[7] has measured growth rate and cap formation of *A mediterranea* in the presence of kinetin and gibberellin over the range 10^{-9} to 10^{-4} molar He found that the maximum effects on stalk elongation and cap formation occurred at different auxin concentrations

The presence of phosphatase enzymes in *Acetabularia* has been described by Spencer and Harris[8] They found an acid phosphatase (optimum *p*H 5 0) which steadily increased in amount as the cell developed, and an alkaline phosphatase (optimum *p*H 11 7) which only appeared during cap formation This enzyme was also synthesized during cap formation in the enucleate cell

The present communication describes the effect of kinetin on these two enzymes and on cap formation in nucleate and enucleate *A crenulata* The effect of 2,3,5-triiodobenzoic acid (TIB) is also reported At 10^{-4} molar this substance antagonizes plant growth and is toxic at higher concentrations[4] *A crenulata* were grown as previously described[8] The cell density was fifty cells in 100 ml of Erdschreiber medium[9] The necessary amount of kinetin (6-furfurylaminopurine) was added from a stock solution in sterile sea water[7] TIB was dissolved in the minimum volume of sodium hydroxide and was adjusted to *p*H 8 3 with hydrochloric acid, it was then diluted with sterile sea water to give a stock solution The cells were transferred to fresh medium at 14 day intervals Prior to enucleation, the cells were kept in the dark for 10 days The nucleus was removed by amputation of the rhizoid[8] The cells were allowed to recover for 2 days in weak light before addition of the kinetin or TIB This procedure gave a higher recovery rate than when the amputated cells were maintained for 1 day in the dark The cells were collected and the number of caps counted as small (less than 3 mm in diameter) or large (above 3 mm) The phosphatase enzymes were then assayed as previously described[8]

Preliminary experiments showed that kinetin did not affect the cap morphology and a concentration of 10^{-7} molar gave the greatest increase in the rate of cap formation for small nucleate cells The time course for cap formation was therefore followed at 10^{-9}, 10^{-7} and 10^{-5} molar kinetin The results for cells which were initially 7 mm long are shown in Table 1

It can be seen that cap formation is accelerated in the presence of kinetin with the greatest effect at 10^{-7} molar In all cases, cells which were treated with kinetin formed caps on shorter stalks than in the controls The synthesis of acid phosphatase was not greatly affected by the presence of kinetin and again the alkaline phosphatase only appeared when the cell was about to form a cap. Table 1 also shows the effect of kinetin on cells which were 15 and 25 mm long The auxin effect is reduced as the cell matures and is negligible for cells of length 25 mm.

Survival of *Acetabularia* after enucleation necessitates keeping the cells in the dark for 10 days before removal of the rhizoid[10,11] The results obtained for the effect of kinetin on enucleate cells of length 25 mm are shown in Table 2 The growth promotion was greater than for nucleate cells of the same size and cap formation was coupled with the appearance of alkaline phosphatase

The inhibition of growth in the presence of 10^{-6} and 10^{-4} molar TIB is shown for 10 and 30 mm long nucleate cells in Table 3 The results for enucleate cells measuring 25 mm are shown in Table 4 In all cases there was some inhibition of growth at 10^{-6} molar TIB and almost complete inhibition at 10^{-4} molar TIB The inhibition of cap formation also prevented synthesis of the alkaline phosphatase

Table 3 EFFECT OF TIB ON WHOLE CELLS

Table 4 EFFECT OF TIB ON ENUCLEATE CELLS

Weeks	Control			10^{-6} molar			10^{-4} molar		
	%	*p*H 5	*p*H 12	%	*p*H 5	*p*H 12	%	*p*H 5	*p*H 12
0	0	0 2	0 05						
4	10–16	0 23	0 11	4–16	0 2	0 09	0	0 25	0 06
8	16–8	0 3	0 12	5–30	0 4	0 13	0	0 3	0 06

These results show the same morphological changes as those described by Thimann and Beth[4] and Zetsche[7] The principal features are that the greatest enhancement of stalk growth and cap formation take place with different concentrations of kinetin Cap formation is, however, always linked with the appearance of alkaline phosphatase.

Kinetin is probably not normally present in *Acetabularia* because added kinetin causes the caps to form on shorter stalks Thimann and Beth[4] similarly concluded that indole acetic acid was not a native auxin Tandler[12] has described the presence of crystals in the central vacuole which are indole derivatives It was shown by the following experiment that this material was probably not an auxin *Acetabularia* plants, 25 mm long, were homogenized and the cell sap was added, in various proportions, to dishes of cells measuring 10 mm and 20 mm Growth was then followed for 6 weeks During this time there was no obvious difference between control cultures and the treated cells

It is unlikely that the phosphatases are closely associated with the chloroplasts, as shown by the following experiment Cell sap was collected from five hundred cells with caps and was then layered on a gradient of 20 per cent to 40 per cent to 60 per cent sucrose After centrifugation, all the chloroplasts were in the 40 per cent layer, but the phosphatase enzymes were on top of the 20 per cent layer There was no phosphatase activity at all in the chloroplast fraction

Both kinetin and TIB exert specific actions on *Acetabularia* and there is no evidence of bizarre changes in morphology or in enzyme formation This suggests that there are specific mechanisms which are modulated by these compounds These processes which cause stalk elongation or cap formation and synthesis of alkaline phosphatase are probably controlled by separate mechanisms in the cytoplasm and the extent of their activities is regulated, to differing degrees, by the presence or absence of inducers such as kinetin or indole acetic acid

Deficiency of Erythrocyte Nicotinamide Adenine Dinucleotide Nucleosidase (NADase) Activity in the Negro

It has been shown that haemolysates from newborn infants differ from those of adults in that UDPgalactose-4-epimerase (epimerase) is active in the absence of exogenous nicotinamide adenine dinucleotide (NAD) (ref 1). The apparent NAD-independent epimerase activity results from low or absent NADase activity in the haemolysates from newborns[2]

Among a group of control samples from adults, epimerase activity independent of exogenous NAD was found in the haemolysate of one individual, a Negro NADase activity was absent from erythrocytes A preliminary study has shown that reduced or absent erythrocyte NADase activity is common among adult Negroes and that the deficiency may be genetically determined

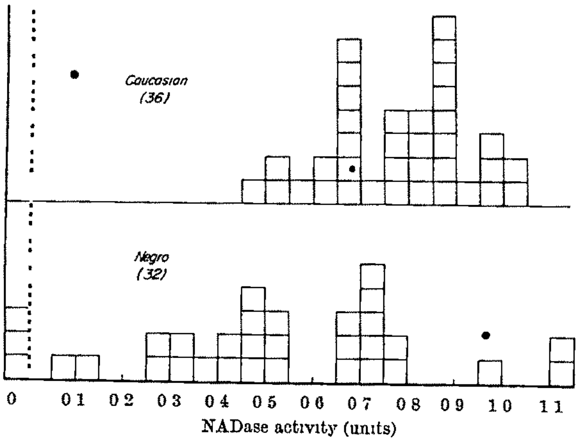

Fig 1 Erythrocyte NADase activity

Haemolysates were prepared from washed erythrocytes as previously described[3] Assay of NADase activity involved incubation in the presence of NAD, followed by determination of the residual NAD concentration In the initial incubation, the reaction mixture consisted of 0 5 μmoles of NAD, 100 μmoles of glycine buffer (*p*H 8 7) and 0 5 ml. of 50 per cent haemolysate in a total volume of 0 8 ml. Incubation was carried out in duplicate for 60 min at 37° C in 3 ml 'Lusteroid' tubes At the end of the incubation period, 2 ml of cold 0 6 normal perchloric acid was added The tubes were stoppered, mixed on a cyclomixer for 20 sec and held in an ice bath for at least 10 min

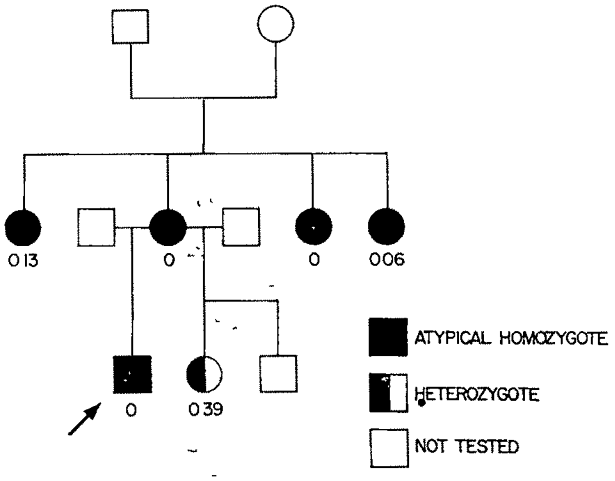

Fig 2 Erythrocyte NADase activity in a Negro family (family *G*) Presumed genotype indicated

NAD was determined according to the method of Minakami *et al* [4] The mixture was centrifuged in the cold at 10,000 r p m for 10 min The supernate was decanted and centrifuged once more at 3,000 r p m at room temperature for 10 min For removal of perchlorate from a 1 ml sample of the supernate, 0 1 ml of 1 molar triethanolamine hydrochloride and 0 1 ml of 5 molar K_2CO_3 were added After 30 min in an ice bath, the precipitate formed was removed by centrifugation for 10 min at 3,000 r p m The concentration of NAD in the supernate was determined by coupling to alcohol oxidation in the presence of an excess of alcohol dehydrogenase The initial concentration of NAD was established on the basis of unincubated control tubes to which perchloric acid had been added at zero time

The activity of haemolysate NADase was expressed as μmoles of NAD disappearing/h/ml of packed red blood cells[5] The validity of the assay was substantiated in a number of instances by simultaneous determination of NAD by the specific cyanide method of Ciotti and Kaplan[6]

The distribution of values found for erythrocyte NADase activity of unrelated healthy adults, both Caucasian and Negro, is shown in Fig 1 The activity range for Negroes spreads more widely than that for Caucasians In three of the thirty-two Negroes no activity was demonstrable

The distribution of values in the Negro sample suggests three groupings For the present purpose, we have arbitrarily designated individuals with values more than 0 65 U as normal homozygotes, those with values less than 0 15 U as atypical homozygotes and those with intermediate values (0 25–0 55 U) as heterozygotes It is

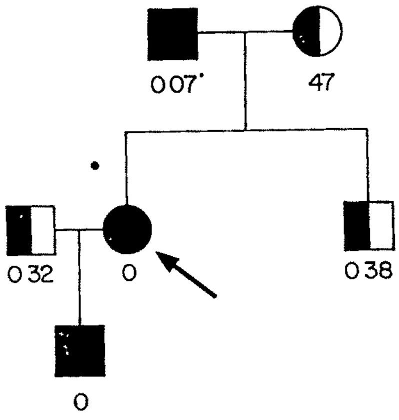

Fig. 3. Negro family *R*.

on this basis that presumed genotypes have been indicated in the pedigrees of the two Negro families so far studied.

The family of the original propositus is presented in Fig. 2. Erythrocyte NADase values were very low or absent for his mother and for each of his three maternal aunts. His half-sister was found to have an intermediate value (0.39 U). In the second family (Fig. 3), very low or absent erythrocyte NADase activity was found for the propositus, for her father and for her son; values for her mother, brother and husband were intermediate (0.47, 0.38 and 0.32 U, respectively). The distribution of activity among family members, particularly in the second family, suggests autosomal transmission.

The present study is a preliminary one, but the data indicate that the pattern of distribution of values among the Negroes so far examined is markedly different from that among the Caucasians.

The function of NADase in the red cell is not known, and significance of the present results in terms of the erythrocyte is uncertain. In the newborn Caucasian infant, erythrocyte NADase activity is low to absent, but normal adult levels are reached within the first year of life[2]. Burton has reported a similar finding for the enzyme in the developing rat brain[7]. Multiple forms of NADase have been demonstrated in mammalian tissues[8]. The availability of erythrocytes with altered NADase activity may provide a basis for establishing the function of this enzyme in the red cell.

Proteins and Haemoglobins of Salmon–Trout Hybrids

SPECIMENS of the salmon (*Salmo salar*)–sea trout (*S. trutta*) which were developed by Dr D. J. Piggins of the Salmon Research Trust were obtained from a small lake at Galmoylestown, near Mullingar, County Westmeath. The eye lens, muscle and serum proteins and haemoglobins of these F_2 2 yr old (2+) specimens were compared with those of adult salmon from the River Lee, County Cork, and with those of 2+ specimens of brown trout (*S. trutta*) from the Fanure Fish Farm, Roscrea, County Tipperary.

The proteins of the eye lens were separated electrophoretically in agar gel on microscope slides with phosphate buffer *p*H 7.3 at 5 m amp per slide for 40 min using the bath described by Koch *et al.*[2] and the technique of Scheidegger[3]. Muscle extracts were prepared from the middle of the body near the dorsal fin and electrophoresis was carried out in polyacrylamide gel[4] using 0.05 molar veronal buffer at *p*H 8.6 at 30 m amp for 120 min. Electrophoresis of serum proteins was also carried out in polyacrylamide gel. The electrophoretograms were scanned in the automatic fully integrated 'Chromoscan' recorder using a slit width of 1/20 mm, a 3 : 1 gear ratio and cam 5–034 *A*. The 'Chromoscan' patterns have been reduced in the figures to one-quarter the original size.

The haemoglobins were analysed using two different supporting media; micro starch gel and micro agar gel. For starch gel studies, the haemolysates were made up in *tris*-hydrochloric acid buffer at *p*H 8.2: some fractions migrated towards the anode and others migrated towards the cathode from the point of application. The technique used was the micro starch gel method of Koch, Bergstrom and Evans[5]. With the micro agar gel technique, we used the bath described by Koch *et al.*[2] and the method of Scheidegger[3]. In agar gel all the haemoglobin fractions travelled towards the negative pole.

In Fig. 1 is shown the electrophoretic pattern of the lens proteins. The salmon shows at least eight components, the trout at least seven and the hybrid a minimum of ten. The hybrid pattern is not therefore like the parental patterns, nor does it seem to be a simple mixture of the two parental proteins. This is in contrast to what we have found in the case of the bream (*Abramis brama*)–

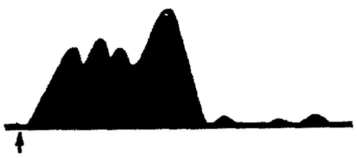
Muscle salmon–trout hybrid



Muscle brown trout 2+

Fig 2 Electrophoretic patterns of the muscle proteins of salmon, trout and the salmon–trout hybrid

rudd (*Leuciscus erythrophthalmus*) F_1 hybrid whose pattern resembles the parental patterns which themselves are very similar These results are now in preparation.

In Fig 2 are shown the muscle protein patterns of the three fishes There is relatively little difference between the patterns of the two parental species, and the hybrid pattern is also very much like those of the parents Rabaey[6] using agar gel electrophoresis found that closely related species had similar patterns, although Connell[7] using the Tiselius method found that patterns of related species seemed to be as dissimilar as those of unrelated species. Greenberg and Kopac[8] found that in the genus *Xiphophorus* (using paper electrophoresis with a phosphate buffer at pH 6 5) hybrid forms showed characteristics of both parental species

The electrophoretic patterns of the serum proteins of the salmon, the sea trout and their F_2 hybrid are shown in Fig 3 It will be seen that the hybrid pattern is more like that of the trout than that of the salmon and does not seem to be a simple mixture of the parental patterns one new hybrid serum protein fraction does, however, occur. This is similar to our finding, the literature on which is now being prepared, that in the rudd–bream hybrid, the hybrid serum protein pattern resembles that of the bream. Sanders[9] in a study of three trout species and their hybrids, found that the hybrids gave serum protein electrophoretic patterns characteristic of one of the parental types Nyman[10] studied a roach (*Leuciscus rutilus*)–rudd hybrid, the splake, a hybrid between eastern brook trout *Salvelinus fontinalis* and the lake trout (*S manaycush*) and the bröding, a hybrid between *S fontinalis* and the char (*S alpinus*) In the serum protein patterns the roach–rudd hybrid showed perfect summation, the splake pattern was indistinguishable from *S fontinalis* and in the broding "not every band system is a summation of the parental patterns".

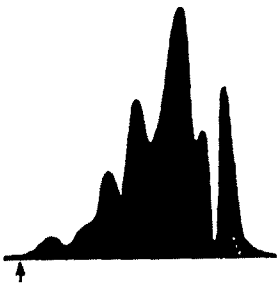
Nyman[11] reported that the F_1 salmon–brown trout hybrid serum protein pattern is a simple combination of the proteins of both parents He later[12] noted that some of these proteins seem to be determined by the same genes in both parental species and only one band is present in the F_1 hybrid in a concentration equal to that in the parents He found that in the F_2 generation, selection occurs against the salmon proteins of the serum and the kidney, liver and serum esterases, but others have shown that this is not true of the blood groups[13]

It may be seen from Fig 4 that no new hybrid haemoglobin was found using the starch gel technique, the hybrid pattern is not, however, just a mixture of the two parental patterns On both the anode and the cathode side, only four of the five salmon fractions are present in the hybrid and the C_1, C_2 and C_4 fractions of the trout do not occur in the hybrid The micro agar gel technique also shows that there is an overall reduction in the number of fractions in the hybrid, as seen in Fig. 5 Koch *et al* have shown that the relative quantities of the components, which at pH 8 2 migrate to the anode, decrease as the salmon and sea trout grow.

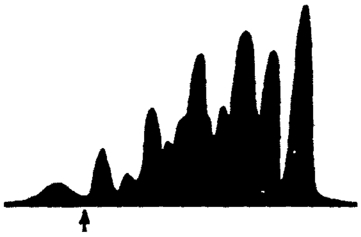
Sick, Frydenberg and Nielsen[14] studied the haemoglobin patterns of the plaice (*Pleuronectes platessa*) and the flounder (*Platichthys flesus*) and their natural hybrids Nearly all the hybrids (thirty-three out of thirty-four) showed the same haemoglobin pattern which clearly differed from that obtained by running an *in vitro* mixture of haemoglobins from the two parent species The authors explained that the presence of new haemoglobins in the hybrid was evidence for the occurrence of at least two different sub-units in the tetrameric haemoglobin molecules of the parental species The single deviant pattern found among the 327 individuals which were studied was recognizable morphologically as a hybrid which could have been the result of a mating between two hybrids or between a hybrid and one of the parent species

Manwell *et al.*[15] noted that there was little evidence for the formation of any new hybrid protein in various animals. These authors studied the haemoglobins of some hybrid birds and fishes to investigate the possibility that new haemoglobins might arise in hybrids from recombinations of the different polypeptide chains and be significant in explaining some aspects of hybrid vigour

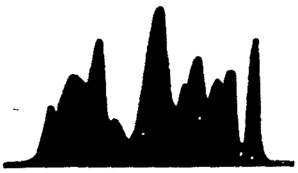
In a study of four species of centrarchid fishes, it was found[12] that in most cases the F_1 hybrids yielded a



Serum salmon normal



Serum salmon–trout hybrid



Serum brown trout 2+

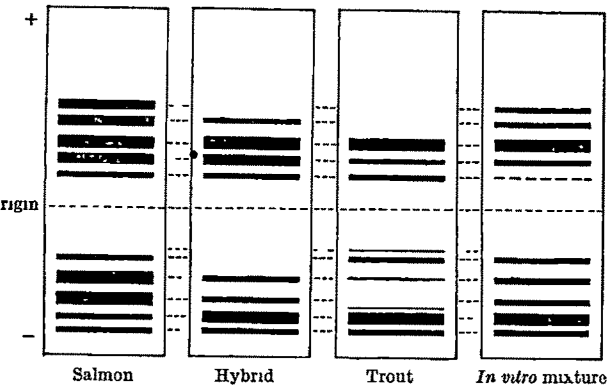

Fig 4 Haemoglobin patterns of salmon, trout, salmon–trout hybrid and an *in vitro* mixture of salmon and trout blood in starch gels

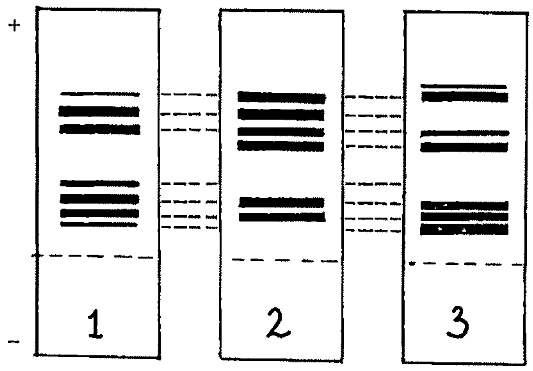

Fig 5 Haemoglobin patterns of salmon (1), trout (3) and salmon–trout hybrid (2) in agar gels C_1 and C_2 of the hybrid pattern correspond to the C_2 and C_3 of the salmon and trout patterns The C_3 component of the hybrid has a migration rate similar to the C_4 of the trout, while the C_5 fraction of the hybrid has comparable components in C_5 of the salmon and C_5 of the trout

haemoglobin pattern which was identical to that obtained by simply mixing the haemoglobins of the two parents In some of these crosses, however, the electrophoretic properties of 25–40 per cent of F_1 hybrids were different from those of the parental species

"Artificial hybridization" of haemoglobins from the small mouth bass *Micropterus dolomieu* and the large mouth bass *M salmoides* was achieved by mixing haemolysates and leaving the mixture in pure carbon monoxide for several days The new haemoglobins which were produced seem to be identical with those of the red-eyed bass *M coosae* and the spotted bass *M punctulatus* which, it is suggested, may have evolved from hybrids of the large-mouth and small-mouth bass Hybrid fishes do not seem to have any unique haemoglobin peptides, which again suggests that polypeptide chain recombination rather than biosynthetic interaction is responsible for the appearance of new hybrid haemoglobins Manwell *et al*[15] have shown that in some hybrid fishes there is better blood gas transport by the new haemoglobin, thus providing an understanding of the nature of hybrid vigour at the molecular level[15]

Vitamin B_{12} Content of Aqueous Humour

THE vitamin B_{12} content of the aqueous humour of the eye does not seem to have been estimated before Samples of aqueous humour and blood were obtained at operation in sixteen patients having cataract extraction, the serum and aqueous concentrations of vitamin B_{12} were determined by biological assay using *Euglena gracilis* The results are presented in Table 1. It is interesting that the average value (29 9 pg/ml) is of the same order as that found in cerebiospinal fluid (21 pg/ml) by Kidd *et al*[1]

There was no significant statistical correlation between the concentrations in the blood and the aqueous (r= 0 097, $P \gg 0{\cdot}10$), but it must be admitted that the method of assay is not very accurate at low concentiation It is also emphasized that all the patients had cataracts and so most were elderly It does not seem justified to risk paracentesis and removal of aqueous humour from normal human eyes in order to obtain more "physiological" values Samples of aqueous humour were obtained through a cannula and dry-sterilized syringe in the early stages of the operation—before it, several instillations of guttae 2 per cent homatropine and cocaine 4 per cent hydrochloric acid and often 10 per cent phenylephrine had been given, and also a retrobulbar injection of 1·5 per cent xylocaine with adrenaline 1 200,000 Sparine (25 mg) was given by mouth on the evening before operation, 1 h before the operation 50 mg of pethidine with 50 mg of phenergan were injected intramuscularly Great care was taken to reduce contamination of the cannula with blood from the operative field to an absolute minimum, it was probably negligible

It is possible that abnormally low values of vitamin B_{12} in the aqueous humour could be found in patients suffering from "tobacco amblyopia", in view of the low concentrations of serum vitamin B_{12} found in this disease[2] and the improvement following treatment with vitamin B_{12} (refs 2 and 3) It is unlikely that there will be an opportunity to obtain samples of aqueous humour from patients with that disease, but the data available in normal patients were further analysed according to the smoking habits of the subjects The mean aqueous concentrations of vitamin B_{12} were 20 2 pg/ml for the smokers and 34 3 pg/ml for the non-smokers (t=1 12, P>0 10) The difference is not regarded as being more than suggestive, but it will be seen that the five smokers showed aqueous

Table 1 AQUEOUS B_{12} DETERMINED BY *Euglena* ASSAY

16	72	F	—	564	28

Ranges, 12–60 pg/ml Crude mean, 29 9 pg/ml concentrations of B_{12} of less than 30 pg/ml , whereas eight of the eleven non-smokers had concentrations greater than 25 pg/ml If confirmed, this observation may be relevant in the elucidation of the pathogenesis of tobacco amblyopia

The underlying reason for this investigation, apart from intrinsic interest, was the suggestion (mentioned by Phillips and McKenzie[4]) that the mechanism of tobacco amblyopia, or any toxic amblyopia, is a toxic effect on the retina of, say, cyanide or other toxin, which enters the eye with the aqueous humour and affects the retina, especially the macular area, from its vitreous surface. There is evidence for a flow of fluid from vitreous to retinal blood vessels and through retina to choroid[5] This might explain why the retina is so selectively affected by certain toxins, the blood-aqueous barrier is not so high or so selective as the blood–retina barrier Similar considerations might apply to the blood–cerebrospinal fluid barrier and blood–brain barrier The response of the levels of aqueous B_{12} to injected hydroxocobalamin and cyanocobalamin is being studied, together with thiocyanate levels

Iron Binding Properties of Saliva

Gastric juice of healthy people contains a high molecular weight iron binding protein "gastroferrin"[1] A role for the gastric iron binding protein in the regulation of iron absorption has been proposed[2,3], and alterations in its production have been described in clinical conditions of iron deficiency[3] and iron overload[2] The gastric juice obtained for the studies previously reported was free of saliva. Normally, however, swallowed saliva contributes substantially to the total volume of secretions present in the stomach It was therefore decided to investigate the possible iron binding properties of this secretion The effect of acid-peptic digestion on the iron binding properties of saliva was also studied because of the possibility that hydrochloric acid and pepsin secreted by the gastric mucosa react with the saliva present in the stomach.

Whole saliva was collected from thirty-five normal subjects who expectorated into a beaker Saliva was found to possess marked iron binding ability when this was measured by a standard iron-59 solubility test previously described[4] Iron binding capacity varied from 0 03 to 0 15 mg of Fe^{+++}/ml of saliva (mean 0 08 mg of Fe^{+++}/ml)

In the next set of experiments, saliva which had been labelled with iron-59 was resolved by molecular sieving through a column of 'Sephadex *G*-200' The relative protein content of the eluted fractions was determined by optical density measurements at 280 mμ and the iron content by measurement of the gamma activity of the iron-59 label A constant elution pattern of two protein peaks was obtained, a totally excluded peak of molecular weight greater than 200,000 and a peak of lower molecular weight Both peaks contained bound iron-59 (Fig 1) In contrast, iron binding in gastric juice occurs only in the high molecular weight fraction[1]

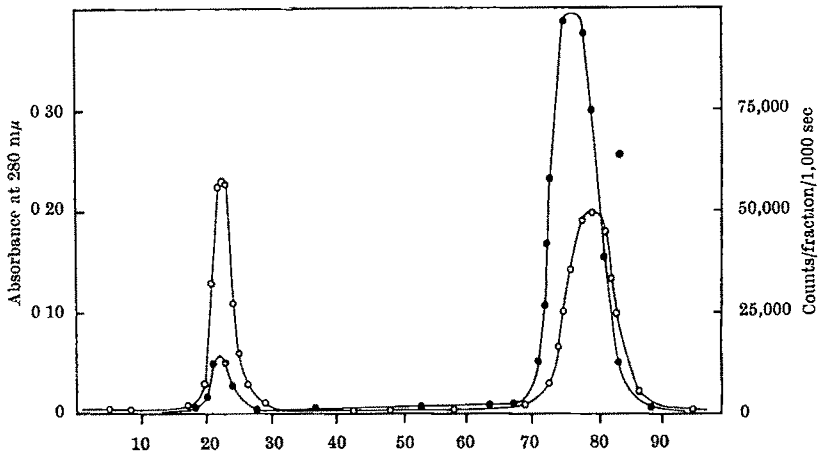

Fig 1 Filtration on 'Sephadex *G*-200' of whole human saliva labelled with iron-59 Sample volume was 3 ml Column dimensions were 2 5 × 40 cm Buffer, physiological saline buffered to *p*H 8 0 with 0 02 molar HCl/NH_4OH Fractions (3 5 ml) were collected at a flow rate of about 30 ml /h ○, UV absorbance, ●, radioactivity

When saliva was labelled with iron-59 and subjected to digestion with 0 02 per cent w/v pepsin in 0 1 molar HCl for 1 h at 37 5° C, the protein content of the high molecular weight fraction was almost abolished The absolute amount of iron-59 bound to this fraction was, however, not significantly altered The high molecular weight iron binding substance in saliva is therefore resistant to acid-peptic digestion The second fraction of lower molecular weight increased after acid-peptic digestion and also retained its iron binding activity

Experiments with polyacrylamide disc gel electrophoresis[5] of saliva labelled with iron-59 using standard 7 5 per cent polyacrylamide gel columns and *tris*-glycine buffer, *p*H 8 3, showed that iron binding occurred in the slow moving components These components have been shown by other workers to contain glycoproteins[6].

The total amount of high molecular weight iron binding substance secreted in saliva in 24 h is sufficient to bind approximately one tenth as much iron as can be bound by the estimated 24 h secretion of gastroferrin. The high molecular weight iron binding substance in saliva might have a function in health and disease similar to that of gastroferrin, both because of its molecular weight and because it is resistant to acid-peptic digestion

PHYSIOLOGY

Effects of Prostaglandins on Human Bronchial Muscle

INTRAVENOUS administration of prostaglandin $F_{2\alpha}$ ($PGF_{2\alpha}$) increases bronchial resistance in the cat[1] and air overflow volume in the Konzett–Rossler preparation of guinea-pig lungs *in vivo*[2] These effects suggest but do not prove that $PGF_{2\alpha}$ contracts bronchial muscle They might be caused by changes in fluid distribution in the lungs Main[3] and Horton and Main[4] showed that prostaglandins E_1, E_2, E_3, $F_{1\alpha}$ and $F_{2\alpha}$ relax cat isolated trachea Because of the uncertainty about the action of $PGF_{2\alpha}$ on tracheobronchial muscle and because this prostaglandin and PGE_2 have been found in human lungs[5,6], where they may affect the smooth muscle of the bronchial tree, we studied their effects on human isolated bronchial muscle We also studied the effects of PGE_1 and of mixtures of PGE_1 or PGE_2 with $PGF_{2\alpha}$ on this smooth muscle preparation

Pieces of bronchus (1–3 mm in diameter) were cut spirally and suspended in Krebs–Henseleit solution at 37° C in a 25 ml bath aerated with 5 per cent carbon dioxide in oxygen Fresh solutions of test substances in 0 9 per cent w/v sodium chloride in water were added to the bath for 3–6 min To measure contraction isotonically, a weighted thread from the muscle was passed over a pulley wheel, which was fixed coaxially to the spindle of a variable rotary transformer (Elliott) The output from the transformer was recorded on a self-balancing servo-potentiometric pen recorder (Rikadenki) Fuller details of this method will be described elsewhere[7]

After a variable latency of up to 1 min, during which the muscle sometimes relaxed slightly, $PGF_{2\alpha}$ (0 8–800 ng/ml) contracted human bronchial muscle, the response increasing with increasing dose Comparable doses of PGE_1 relaxed the muscle PGE_2 usually relaxed it, but was rather less active than PGE_1 When mixed with $PGF_{2\alpha}$, either prostaglandin E_1 or E_2 reduced the contraction caused by $PGF_{2\alpha}$ (Fig 1) Neither atropine (1 μg/ml) nor mepyramine (1 μg/ml) lessened the response to $PGF_{2\alpha}$, so the prostaglandin did not act by stimulating cholinergic nerves or by liberating histamine

The slow reacting substance produced in anaphylaxis of isolated lung (SRS-A) is not yet chemically purified and identified, but has been described as an acid with some lipid characteristics[8] and might therefore be related to the prostaglandins Because both SRS-A (refs 2 and 9) and $PGF_{2\alpha}$ contract human bronchial muscle, we tested whether cross-tachyphylaxis could be induced between them, using SRS-A prepared as previously described[2] Tachyphylaxis to either SRS-A or $PGF_{2\alpha}$ could be induced by prolonging by a factor of about ten the time of exposure of the muscle to a high dose of the substance Pieces of muscle made insensitive to $PGF_{2\alpha}$ responded to SRS-A (Fig 2) and vice versa The absence of cross-tachyphylaxis confirms the conclusion reached on other grounds[2], that these two substances from lung are distinct After tachyphylaxis had been induced to $PGF_{2\alpha}$, prostaglandins E_1 and E_2 continued to relax the bronchial muscle (Fig 2)

In these experiments, $PGF_{2\alpha}$ contracted, whereas PGE_1 and PGE_2 relaxed, human isolated bronchial muscle $PGF_{2\alpha}$ occurs in human lungs[5,6] and it may be concerned in conditions involving bronchoconstriction, such as bronchial asthma PGE_2 is also present in human lungs[6], so a functional relationship between the contractant $PGF_{2\alpha}$ and the relaxant PGE_2 seems possible

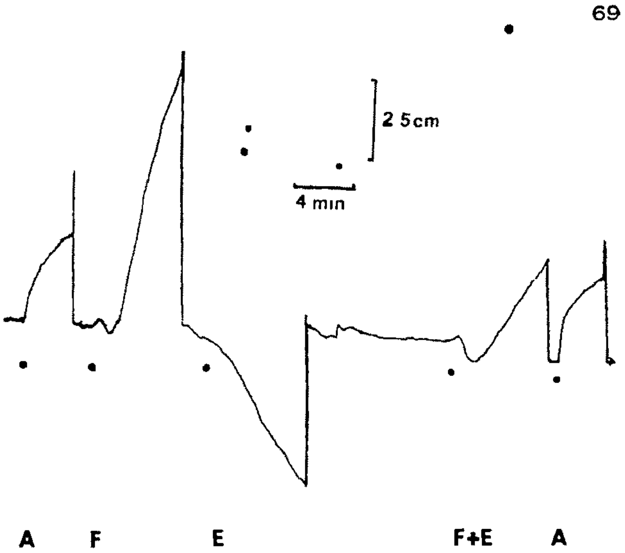

Fig 1 Human isolated bronchial muscle in a 25 ml bath Responses to prostaglandins $F_{2\alpha}$ ($PGF_{2\alpha}$) and E_1 (PGE_1) and to a mixture of the two A, 10 μg of acetylcholine, F, 20 μg of $PGF_{2\alpha}$, E, 10 μg of PGE_1, ●, drug added Recording magnification × 40

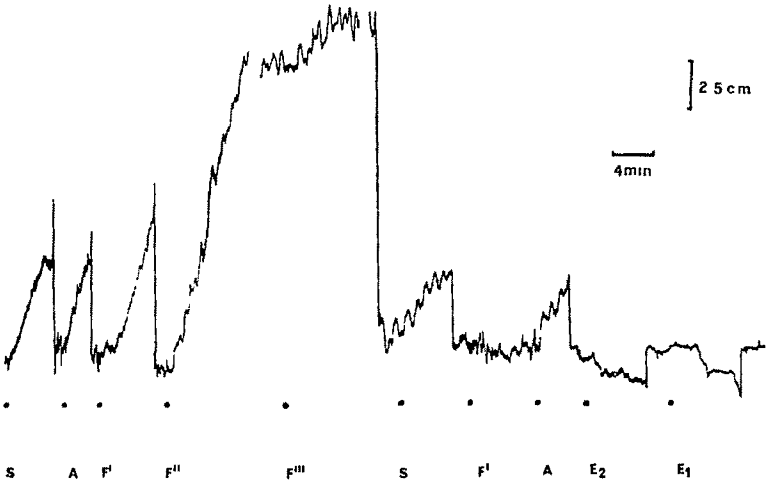

Fig 2 Human isolated bronchial muscle in a 25 ml bath Development of tachyphylaxis to $PGF_{2\alpha}$ without loss of response to slow reacting substance in anaphylaxis (SRS-A) or to PGE_1 or PGE_2 During the first break in the record, exposure to 2 μg $PGF_{2\alpha}$ continued for 5 min, during the second break in the record, exposure to 20 μg $PGF_{2\alpha}$ continued for 15 min S, 0 25 mg of SRS-A, A, 1 μg of acetylcholine, F', 1 μg, F'', 2 μg and F''', 20 μg of $PGF_{2\alpha}$, E_2, 0 5 μg PGE_2, and E_1, 0 5 μg of PGE_1, other details as in Fig 1

We thank Dr J E Pike, of the Upjohn Company, and Professor B Samuelsson, of the Kungl Veterinarhogskolen, Stockholm, for giving prostaglandins and Mr J W Jackson and Sister J DeMulder, of Harefield Hospital. for their help in obtaining specimens of human lung We also thank Mrs S Foard, Dr W A Jones, Mr G G Matthews, Mr M. A E Palmer, Mrs P J Piper and Mr B F Singer for help in preparing partially purified SRS-A

New Test for Biological Identification of Bradykinin

In 1961, Boisonnas, Guttmann and Jaquenoud[1] first synthesized bradykinin and other syntheses have since been recorded[2-4] In these studies the contracting effect of this substance on the isolated uterus of a rat or the ileum of a guinea-pig has, among other tests, been taken as evidence of identity with bradykinin which was isolated from plasma, and as a measure of its biological activity As will be shown here, however, this sole criterion may not suffice to characterize the peptide

Recently, we determined the biological identity and activity of bradykinin which was synthesized by Fridkin, Patchornik and Katchalsky according to a new method (presented at the International Symposium on the Pharmacology of Hormonal Polypeptides and Proteins, Milan, September 14, 1967, results to be published) The ileum of a guinea-pig which was suspended in a 5 ml organ bath of Tyrode solution at 35° C was used as the test object Contractions were recorded on a kymograph by means of a frontal writing lever Drugs were allowed to act for 1 min and then the preparation was washed twice The time cycle was 5 min Solutions of all substances were made up in saline Bradykinin Sandoz and a sample prepared by Sakakibara and Inukai[4] served as reference compounds

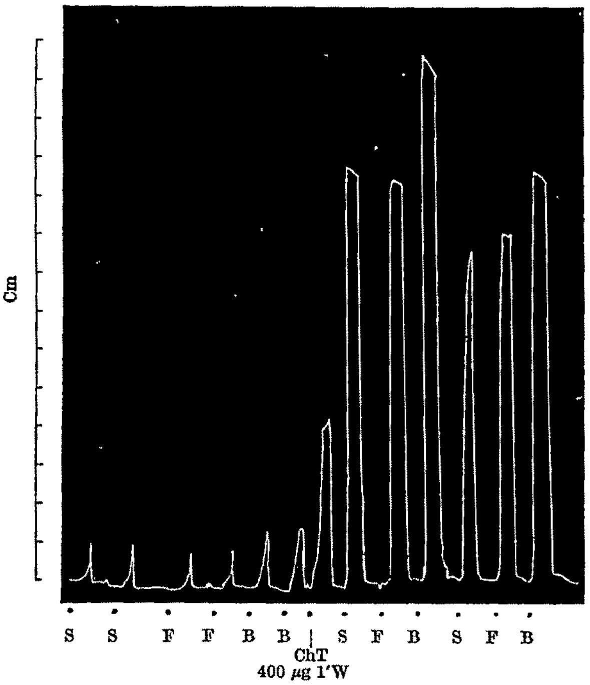

Fig 1 Responses of the isolated ileum of a guinea-pig to three different specimens of bradykinin (20 µg), namely that of Sakakibara and Inukai (S), Fridkin, Patchornik and Katchalsky (F) and Sandoz (B) After each contraction the preparation was washed twice Note that after the presence of 400 µg of chymotrypsin for 1 min (ChT 400 µg 1'W), responses were about ten times higher than that of control

The material which was obtained at the final step of the new synthesis caused contraction of the isolated gut in doses of 7 to 15 ng The magnitude of the responses closely compared with those elicited by corresponding amounts of bradykinin Sandoz When 500 µg of chymotrypsin was introduced into the bath, however, the subsequent contractions elicited by the test compound did not increase but in fact decreased In contrast, those provoked by bradykinin Sandoz were five times higher than those of the control These experiments indicated that the test substance was not identical with the reference substance Re-examination of the material revealed that the *p*-nitrobenzyl group which was attached to the terminal arginine had not been removed after treatment with hydrofluoric acid[5] The material was therefore reduced in the presence of palladium and barium sulphate, it was purified in a column of 'Amberlite *IRC*-50' and lyophilized The product was tested on the isolated ileum in doses of 5 to 20 ng and elicited responses similar to those of the two reference bradykinins Furthermore, after the presence of chymotrypsin, all three compounds behaved identically they elicited contractions which were eight to ten times larger than those of control Thus the identity of all three specimens of the peptide could be established with certainty Fig 1 illustrates a typical experiment

This work supports a previous suggestion[6] on the usefulness of employing chymotrypsin as a specific sensitizer of the isolated ileum of a guinea-pig for the biological identification of bradykinin It should be remembered that no specific antagonist of bradykinin is at present available Moreover, it can also be inferred that the present biological test for identification of bradykinin, which consists of the disappearance of its contracting activity on smooth muscle on incubation with chymotrypsin, might be misleading In the present work, for example, Phe-Arg bond of the *p*-nitrobenzyl blocked bradykinin could readily be split by chymotrypsin, rendering it inactive on smooth muscle, even though it is not identical with the pure peptide

I thank Dr M Fridkin for providing me with the bradykinin which was prepared by Sakakibara and Inukai

Changes in Iron Metabolism in Natives of 13,000 ft. brought down to Sea Level

Iron metabolism in natives of high altitudes (14,900 ft) decreased when they were brought down to sea level[1,2] The values for the plasma iron and the plasma iron turnover rate obtained by Huff *et al* [1] were higher than those reported by other workers, but this may have been caused by storage and shipment of the samples

In experiments carried out in the north of Argentina from 1960 to 1963, we studied the iron metabolism of high altitude dwellers during the first 13 days after descent to sea level We had a greater number of volunteers and a more homogeneous population than in previous work Thirty-two high school students born and living at 13,000 ft (Mina aguilar, Argentina) served as volunteers None had ever worked in the mines and all played football or basketball Chest X-rays and physical and laboratory examinations confirmed their good health The average weight was 58 kg, height, 164 cm, and age, 18 yr Erythrokinetic studies were performed at high altitudes and afterwards the volunteers were flown to sea level. On days 3, 8, 10 and 13 after the descent the ferrokinetic measurements were repeated. Daily reticulocyte counts were performed throughout the experiment.

The plasma iron turnover (P.I.T.) rate was determined by the method of Huff *et al.*[3], and circulating red cell mass and blood volume by the method of Donohue *et al.*[4]. The plasma volume was computed as an average of the extrapolating method of Huff *et al.*[3] and from the blood volume and peripheral haematocrit[4]. The serum iron level was measured by Schales's technique[5].

At high altitudes, haematocrits, reticulocytes, blood volume and P.I.T. rate were lower than those found previously[1,2] because the measurements were taken at 13,000 as against 14,900 ft and because the volunteers were younger.

Table 1. OBSERVATIONS IN NATIVES OF 13,000 FT BROUGHT DOWN TO SEA LEVEL

	High altitude	Sea level Day 3	Day 8	Day 10	Day 13
No. cases	32	9	12	7	4
Haematocrits (%)	53 ± 0.7*	53.5 ± 0.8	50.5 ± 0.6	51.0 ± 1.0	50.5 ± 0.7
Plasma iron (μg %)	100 ± 8	120 ± 15	138 ± 15	129 ± 6	123 ± 14
Plasma volume (ml./kg)	38 ± 1.8	39 ± 1.6	44 ± 1.8	41 ± 6.1	43 ± 3.2
Red cell volume (ml./kg)	36 ± 2.2	37 ± 1.8	35 ± 3.1	35 ± 2.1	38 ± 2.3
$T\frac{1}{2}$ ^{59}Fe (min)	69 ± 4	145 ± 21	148 ± 14	329 ± 72	343 ± 78
P.I.T. rate (mg iron/day/kg)	0.58 ± 0.14	0.40 ± 0.14	0.38 ± 0.09	0.20 ± 0.11	0.18 ± 0.03

P.I.T. = plasma iron turnover.
* Standard error.

Table 1 shows a 20–30 per cent rise in plasma iron during the sojourn at sea level. P.I.T. rate decreased, and iron-59 clearance increased gradually, reaching six times the high altitude values, between days 10 and 13 at sea level. Red cell volume remained constant throughout the period, with an increase in plasma volume and consequently a decrease in haematocrit. Reticulocytes (Table 2) relate fairly well with the changes in P.I.T. rate.

Table 2. RETICULOCYTE COUNTS IN NATIVES OF 13,000 FT BROUGHT DOWN TO SEA LEVEL

High altitude 0.7 ± 0.1

Sea level

Day 1	0.4 ± 0.06	Day 7	0.2 ± 0.08
Day 2	0.5 ± 0.1	Day 8	0.2 ± 0.02
Day 3	0.2 ± 0.07	Day 9	0.1 ± 0.03
Day 4	0.3 ± 0.09	Day 10	0.1 ± 0.02
Day 5	0.3 ± 0.04	Day 11	0.2 ± 0.01
Day 6	0.3 ± 0.05	Day 12	0.2 ± 0.02
		Day 13	0.1 ± 0.02

Our results show a relationship between hypoxia and erythrokinesis in permanent dwellers at 13,000 ft. Red cell production was inhibited for the first 2 weeks when the polycythaemic volunteers were brought down to sea level.

Prostaglandin Content of Particulate and Supernatant Fractions of Rabbit Brain Homogenates

WHOLE rabbit brains were homogenized in 0.32 molar sucrose solution, and subcellular fractions were prepared by centrifugation by the method of Gray and Whittaker[1]. Prostaglandins were extracted from the homogenates and from the various fractions by solvent partition and further purified by chromatography[2].

Extracts of rabbit brain homogenates showed prostaglandin-like activity when assayed biologically on the rat isolated fundal strip preparation. On silicic acid column chromatography, two main peaks of biological activity were detected, corresponding to the elution rate of pure prostaglandins E and F respectively. On thin-layer chromatography using plates of silica gel impregnated with silver nitrate, zones corresponding to prostaglandins E_2 and $F_{2\alpha}$ contained more than 90 per cent of the biological activity, confirming the report of Ambache, Brummer, Rose and Whiting[3]. The homogenates were estimated to contain 500 ng prostaglandin $F_{2\alpha}$ and 75 ng prostaglandin E_2/g of brain tissue. When the brain was macerated or homogenized in 96 per cent aqueous ethanol instead of sucrose, similar amounts of prostaglandins were recovered. There was no evidence in our experimental conditions for inactivation or new synthesis in the sucrose homogenates as reported by other workers[4].

In each of four experiments the final supernatant after centrifuging at 100,000*g* (4° C for 2 h) contained between 80 and 90 per cent of the total prostaglandin activity of the homogenates. Substances with chromatographic and biological properties identical to prostaglandins E_2 and $F_{2\alpha}$ were identified in the supernatant fraction, which also contained 80 per cent of the total potassium present in the whole homogenate.

The combined particulate fractions also contained the two prostaglandins. Between 5 and 10 per cent of the biological activity of the whole homogenate was in the fraction *P*2 which, according to electron microscopic evidence[1], would contain mitochondria and nerve endings. Because the amounts of prostaglandin in the *P*2 fraction were so small, further fractionation by sucrose gradient technique has not so far been feasible. The remainder of the prostaglandin-like activity of the particulate fraction was distributed between *P*1 (nuclei and cell debris), *P*3 (microsomes) and *P*4 (ribosomes and post-microsomal fractions).

The combined particulate fraction was treated in three ways in an attempt to release any bound prostaglandin. One sample was frozen and thawed ten times, another was incubated at *p*H 3 and 60° C for 1 h, and a third sample was suspended in water before extraction with ethyl acetate at *p*H 3. None yielded any additional prostaglandin.

As a control, the succinate dehydrogenase contents of the particulate and supernatant fractions were compared with those of the original homogenate. All the enzyme activity of the homogenate was recovered from the particulate fraction.

It is unlikely that the prostaglandin content of the particulate fractions was the result of contamination by supernatant, because washing with sucrose and recentrifugation did not reduce the amount recovered. But the possibility that the prostaglandin recovered from the supernatant originated from a very labile store in one of the particulate fractions cannot be excluded.

Our results differ from those of Kataoka, Ramwell and Jessup[5], who located 30–40 per cent of the prostaglandins in rat cerebral cortex in nerve ending fractions. The results from both laboratories point to a wide distribution of prostaglandins throughout subcellular compartments.

We thank Dr D. A. van Dorp of the Unilever Research Laboratories, Vlaardingen, The Netherlands, and Dr John

E Pike of the Upjohn Company, Kalamazoo, USA, for supplies of prostaglandins used in this investigation.

Modification of Uricaemia and the Excretion of Uric Acid Nitrogen by an Enzyme of Fungal Origin

TREATMENT of hyperuricaemia and gout is aimed at either synthesis or elimination of uric acid Previous attempts at *in situ* destruction of uric acid have remained experimental because of imperfections in the enzymes The therapeutic use of a new uricase or urate oxidase derived from *Aspergillus flavus* has been studied

Urate oxidase was first used in animals in 1949 (ref 1), it transformed uric acid into allantoin An enzyme derived from animals was partly successful in human therapy[2] The activity of these preparations lasted for several hours only and numerous daily injections were necessary

Laboureur and Langlois[3] isolated a urate oxidase from a selected strain of *Aspergillus flavus* which is sufficiently pure and which possesses a high specific activity in animals Its antigenic potential is moderate, toxicity is negligible. It could be produced in industrial quantities

Our work to verify in man the results obtained in animal studies (M Brunaud, personal communication) was conducted on sixty-one hospitalized patients, who all received a stabilized purine diet They were divided into three groups normal, hyperuricaemics, and patients with gout Uricaemia was measured using a modified Liddle[4] enzymatic technique Urate oxidase derived from *Aspergillus flavus* was used for the assay The buffer was at *p*H 8 5 and readings were taken at 285 mµ The solutions injected were sterilized and prepared by a patented process (Clin-Byla Laboratories) and were assayed at 500 units/l Uric acid in the urine was assayed by the same method Urinary allantoin was measured by the method of Gros and Raveux[5] it was separated from uric acid by passage through an anion exchange resin column. Then alkaline hydrolysis converted allantoin into allantoic acid Acid hydrolysis degraded the allantoic acid into urea and glyoxylic acid After ferrocyanide treatment in a strongly acid medium, the phenylhydrazone of glyoxylic acid was oxidized and the optical density of the resulting solution was read at 518 mµ A unit of urate oxidase activity was defined as the quantity of enzyme capable of causing the disappearance of 50 per cent of the substrate (100 µg/5 ml) in 10 min at 30° C at *p*H 8 5

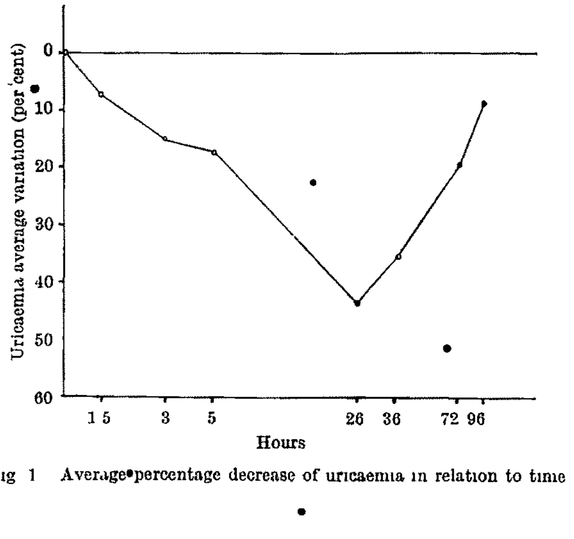

Fig 1 Average percentage decrease of uricaemia in relation to time

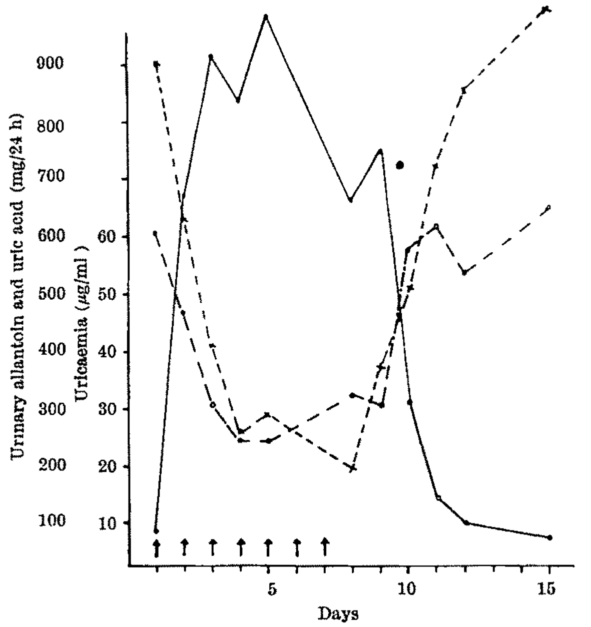

Fig 2 Uricaemia, urinary uric acid and urinary allantoin in a hyperuricaemic patient after seven daily injections (arrows) of 800 U of urate oxidase ●——●, Urinary allantoin, × – – – ×, urinary uric acid, O– –O, uricaemia

Uric acid metabolism in animals used in pharmacodynamic studies is very different from that of man It was therefore difficult to determine active human dosages and methods of administration

Intravenous injections were given at 24 h intervals in order to study variation in uricaemia in relation to various experimental doses The average decrease in uricaemia was for 125 U, 4 8 per cent, for 250 U, 0 per cent, for 500 U, 12 6 per cent, and for 800 U, 40 2 per cent It seems that the activity of the product is manifest above the 500 U level. Its effectiveness is clear at 800 U

The decrease of uricaemia 24 h after intramuscular, intravenous and *per os* administration of 500 U and 800 U doses of enzyme was compared (Table 1)

The efficacy was identical when the enzyme was given intravenously and intramuscularly *Per os* administration was ineffective

We studied the variation of uricaemia in nine patients at different intervals after an intravenous dose of 800 U (Fig 1) Uricaemia decreased quickly during the first 5 h after injection The average decrease was at a maximum

Table 1 URICAEMIA AFTER ADMINISTRATION OF ENZYME BY INTRAVENOUS (I V) AND INTRAMUSCULAR (I M) INJECTION

	500 U		800 U	
	I V	I M	I V	I M
Number of cases	5	6	13	5
Average control uricaemia, (µg/l)	56 8	48	52 2	44 4
Average 24 h post administration uricaemia, (µg/l)	49 6	41 5	31 2	27
Decrease (per cent)	12 6	13 5	40 2	39 2

after 24 h, was still apparent after 48 h, then rose slowly. There was still some enzyme activity after 96 h.

The average variation in urinary uric acid and allantoin in three patients after a single 800 U intravenous dose is shown in Table 2. Urinary uric acid fell during the first 24 h period and a considerable decrease was maintained for 72 h. Urinary allantoin exceeded the control concentration by six or seven times. This demonstrates the mechanism by which urate oxidase destroys uric acid.

After observing the metabolic effects of a single dose of enzyme we studied the uric acid and allantoin modifications after 800 U/day for a test period of 4 or 5 days. Three normal subjects and two hyperuricaemic patients were studied. Table 3 presents data from two normouricaemic subjects after a series of four or five 800 U intravenous injections. The effect on uricaemia, urinary uric acid, and urinary allantoin was recorded for 11 days after the last injection. Fig. 2 is a graphic representation of the same parameters in a hyperuricaemic subject.

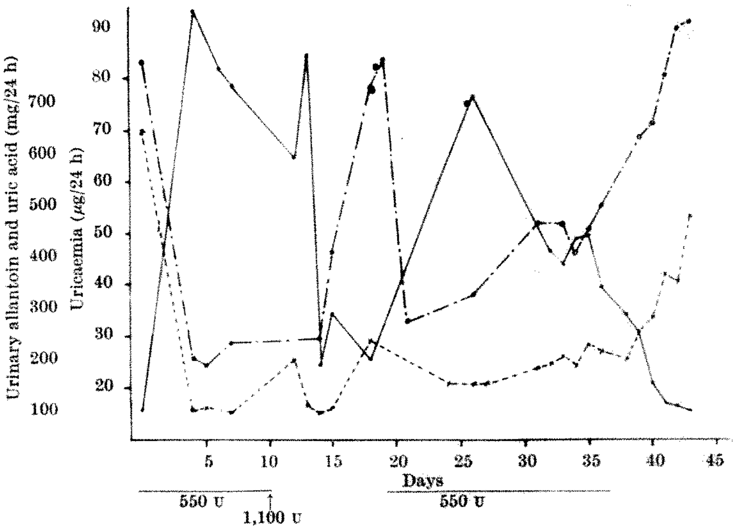

Fig. 3. Uricaemia, urinary uric acid and urinary allantoin in a gouty patient treated daily with urate oxidase. ●——●, Urinary allantoin; × - - - ×, urinary uric acid; ○— · —○, uricaemia.

Uricaemia and urinary uric acid and allantoin decreased in both normal and hyperuricaemic subjects. Uricaemia increased to a level greater than the control 4–7 days after the end of the injection period. Uricuria increased concomitantly with the decreased uricaemia. The urinary uric acid concentration continued to rise even after the uricaemia started to normalize. This asynchronism was constantly observed, suggesting an eventual kidney involvement. The ratio of uricuria to uricaemia is greater than that before treatment even when the uricaemia is at its lowest level. The ratio does not fall after the end of the treatment, so it seems that the enzyme improves the elimination of urinary uric acid.

Table 2. VARIATION IN URINARY URIC ACID AND ALLANTOIN AFTER A SINGLE 800 U INTRAVENOUS DOSE. AVERAGE FOR THREE PATIENTS

	Urinary uric acid				Urinary allantoin			
	24 h	48 h	72 h	96 h	24 h	48 h	72 h	96 h
Variation (%)	−45	−33	−33	−19	+681	+609	+150	+120

Three typical acute gout attacks were interrupted 24 h after daily intravenous injections of 800 U were begun. Four patients with tophaceous gout were given daily injections of 550 U of the enzyme. This dose was selected in order to avoid a very high urinary allantoin concentration and its precipitation. The results were similar in all cases. Graphs of two cases are shown in Figs. 3 and 4. A decrease in uricaemia was observed which was less marked at the end of the treatment.

There was a parallel decrease in urinary uric acid and an elevation of urinary allantoin (up to ten times control concentrations). A later increase in uricaemia was noted, but analyses were not continued long enough after treatment to record the eventual increase in urinary uric acid. The ratio of uricuria to uricaemia was constantly lowered. The urinary elimination of uric acid seems to be a function of the uricaemia concentration in the gouty patients. It is improbable that the enzyme has a different renal action in normal and gouty subjects.

Fundal urate oxidase is negligibly toxic. We observed an immediate allergic reaction in only one of the sixty-one patients injected with urate oxidase for the first time. He had been undergoing treatment for a chronic mycosis and had symptoms of urticaria, oedema of the eyelids, status asthmaticus and dyspnoea. An immuno-electrophoretic study of the patient's serum was negative. Intradermal tests with the enzyme revealed an early tissular sensitization reaction. No disturbances were found in blood nitrogen, blood sugar, differential blood count, blood cholesterol, phosphatases, transaminases, protein electrophoresis or urea clearance in patients treated for long periods.

Two patients with tophaceous gout had attacks, the first immediately after cessation of treatment and the second on the tenth day. Two gouty patients with diagnosed interstitial nephritis had increased urea values which varied from one day to the next. This variation could be attributed to the treatment.

These observations affirm the hypouricaemiant activity of fungal urate oxidase. The conversion of uric acid to allantoin, the presumed mode of action, is confirmed by the presence of increased urinary concentrations of

allantoin. Moreover, the number of uric acid molecules eliminated, either directly or by conversion into allantoin, was increased by an average of four times the pretreatment concentration. This confirms the increase in elimination of purine bases.

A possible renal effect should be investigated. Does the mass action effect of the reduced uricaemia bring about an increased uric acid synthesis from purine bases? The softening of the tophaceous deposits during the treatment suggests that the uratic reserves are preferentially mobilized. Prolonged treatment brings about a slight reduction in urate oxidase activity in normal as well as in gouty subjects. This decrease is probably caused by an antigenic effect observed in immuno-electrophoretic serum studies. The antigenic effect appears to be very labile: iterative treatments give comparable results throughout.

The only practical medication capable of destroying uric acid *in situ* is fungal urate oxidase; its use in the management of gout and hyperuricaemias is indisputable. Urate oxidase alone will probably not be able to solve all problems, but by association with uric acid eliminators or inhibitors of uric acid synthesis, with further clinical studies therapy could be developed.

We thank Mrs M. Rombach for her help in perfecting the analytical procedures used in this project and Mr A. R. Rottman for translating this paper.

Sickling Phenomenon in Sheep

IN 1840 Gulliver[1] described spindle and crescent shaped red cells in the blood of deer. Since then sickling of the erythrocytes of man and deer has become a well recognized and documented phenomenon[2–3]. It is important in man because of its association with sickle cell disease which afflicts about 8 per cent of American Negroes and up to 45 per cent of some African tribes. The disease is caused by the presence in the red cells of an abnormal haemoglobin, haemoglobin S. It was the first disease to be shown to result from genetic influence at the molecular level.

Among domestic animals, sickling has so far been reported in only one species. Holman and Dew[4] reported the appearance of elliptical corpuscles in films prepared from the blood of young goats. These blood films bore some resemblance to those of sickle-cell anaemia, but the phenomenon was restricted in the goat to the period between 1 month and 3 months of age. These workers quoted a personal communication from Dr H. Lehmann, who established that the sickling in the goat was similar to that occurring in deer in that it was dependent on *p*H and could be removed by lowering the *p*H to 6 (ref. 5).

Sickling of red cells has been observed in two of the three breeds of British sheep so far examined. The red cells of sequestrened blood samples from Soay sheep in sealed coverslip-slide preparations developed peculiar oat and fusiform shapes. Samples from thirty-nine Soay sheep have been examined and the red cells in thirty-four of these developed spindle, crescent, holly leaf and matchstick forms. Usually mixtures of varying proportions of the sickled forms that have been reported in the blood of man and deer were seen (Figs. 1–3). In samples from another four sheep the erythrocytes developed more bizarre forms, some of which resembled the outstretched hand (Fig. 4). These changes, best seen when using dark-ground or phase contrast illumination, appeared in 1–18 h in preparations kept at room temperature. The blood from one Soay sheep did not sickle in these conditions.

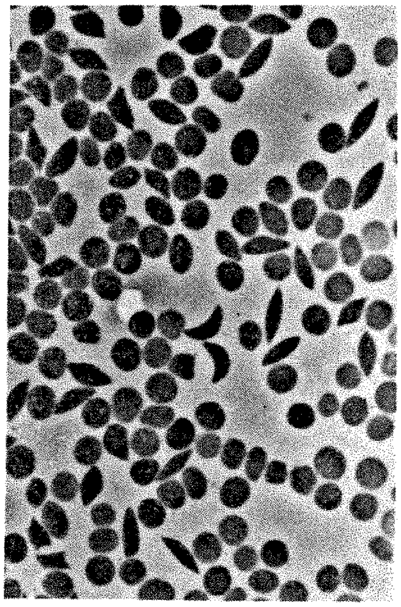

Fig. 1. Early spindle and crescent forms.

The phenomenon has also been seen in twelve out of twelve blood samples collected from recently weaned Swaledale lambs and in three out of nine adult Swaledale sheep from another, old established flock on the North Yorkshire moors. Nothing like sickling was seen in samples collected from twelve Clun Forest ewes apart from the development in four of these, in 24–48 h, of intracorpuscular crystallization of haemoglobin which did not distort the cell outline. An investigation of the incidence of sickling in other breeds is being carried out.

Although the exact physico-chemical conditions conducive to sickling of sheep erythrocytes have not yet been determined, there are indications of a similarity to the conditions necessary for *in vitro* sickling of deer cells. Sickling in sheep cells appears in whole blood saturated with oxygen and in suspensions prepared by diluting whole blood with an equal volume of 0·1 normal Sørensen's phosphate buffer ranging from *p*H 7·4 to *p*H 8·6 (very markedly at *p*H 8·6) but not at *p*H below 7·0. It can be reversed by the addition of a solution of sodium metabisulphite.

There is a marked degree of heterogeneity of haemoglobin in deer blood and sickling in this species can be attributed to the presence within the red cell of a specific haemoglobin component. It is dependent on the percentage oxygen saturation as well as the *p*H of the whole blood or suspending buffer[3,6]. Studies are now being carried out on the electrophoretic pattern of haemolysates prepared from the blood of sickling sheep.

There does not seem to be any correlation between the potassium content of the red cells and the propensity for sickling. In twenty-one Soay blood samples which sickled, eight were in the high red cell potassium category (mean value of 77 ± 2·4 m.equiv./l.) and thirteen were of the low potassium type (mean value 25·4 ± 3·5 m.equiv./l.). Neither do there seem to be any abnormal haematological changes associated wih the phenomenon. Mean values for packed cell volume and haemoglobin concentration were 41·5 ± 3·06 per cent and 13·9 ± 0·26 g/100 ml., respectively. Further studies to ascertain the fragility and thus life span of the red cells in affected sheep are indicated.

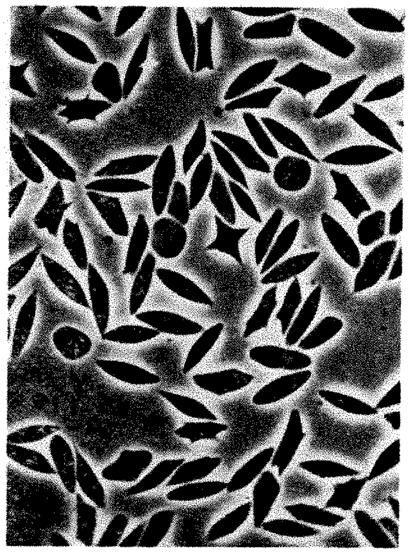

Fig. 2. Mainly spindle and few star and holly leaf forms.

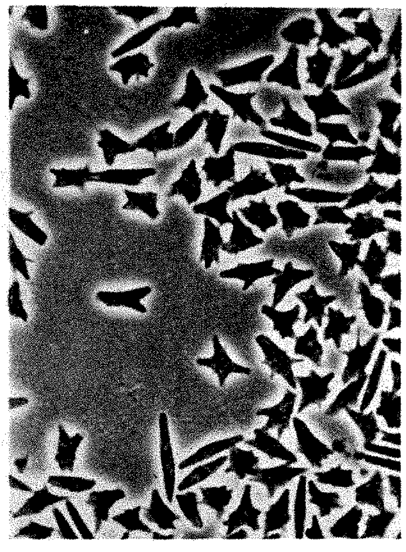

Fig. 3. Mixture of holly leaf and matchstick forms.

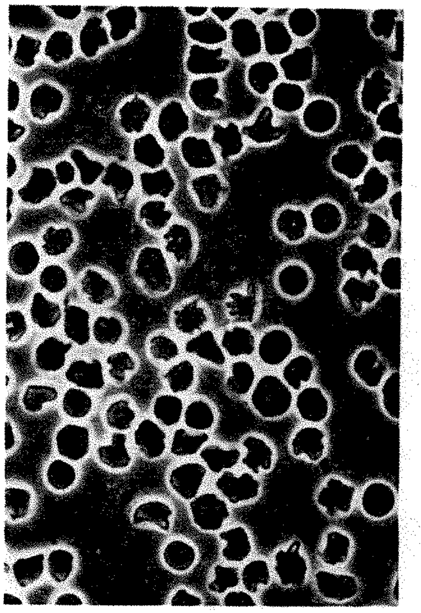

Fig. 4. Bizarre forms; central cell depicting shape of outstretched hand.

Although O'Roke[7] thought that sickle cell anaemia could be a factor in the causation of winter losses of deer in Michigan, a recent report[8] claims that the phenomenon in deer is innocuous because neither haemolytic anaemia nor periodic vascular occlusion occurs, and that the condition should be referred to as "pseudosickling". Nevertheless there may be an association between sickling and the dramatic "crashes" that periodically afflict the Soay population on the Isle of Hirta[9].

I thank Professor Hynes, Department of Zoology, and Professor Phillipson, School of Veterinary Medicine, University of Cambridge, for allowing me access to their flocks of Soay sheep; and Dr R. S. Comline, Department of Physiology, Cambridge, and C. T. McCrea and J. M. Threlkeld, Veterinary Investigation Centre, Thirsk, for collecting and providing blood samples from Soay and Swaledale sheep.

$p\mathrm{O}_2$ Levels in the Placental Circulation of the Mare and Ewe

PREVIOUS work on the oxygen tension in different parts of the placental circulation has been confined almost entirely to sheep and goats, in which the $p\mathrm{O}_2$ gradient between the umbilical and uterine circulations is high[1] and large changes in foetal $p\mathrm{O}_2$ levels are difficult to produce[2-4]. Thus foetal hypoxia occurs only after drastic reduction in maternal arterial blood $p\mathrm{O}_2$, and attempts to raise the foetal $p\mathrm{O}_2$ have met with little success despite the administration of pure oxygen to the mother[2,4]. Even when the foetus is supplied with oxygen by other means, the $p\mathrm{O}_2$ gradient between uterine and umbilical vessels is still present[3].

We have now examined the position in the pregnant mare in which the vascular supply to the diffuse epitheliochorial placenta is very different from that of ruminants. Much of the previous work on the sheep involved removal of the foetus from the uterus and, because it now seems that this procedure may alter foetal oxygen consumption and umbilical blood flow[5], the foetus was kept *in utero* in the present experiments. Measurements of blood oxygen tension in uterine and umbilical vessels were made in four ponies towards the end of pregnancy during different levels of maternal oxygen intake; the results obtained were compared with a similar series of observations on six ewes. All animals were anaesthetized with sodium pentobarbitone and the umbilical and uterine vessels were catheterized using the technique developed by Barron and his colleagues[6] for the ewe. In the mares much longer lengths (15–25 in.) of wider bore tubing (outer diameter, 0·060 in.) were threaded into the main vessels through tributaries exposed by a small incision in the uterine wall. In both species the foetus was undisturbed until the end of the experiment when the position of each catheter was identified. Changes in maternal arterial $p\mathrm{O}_2$ were produced by altering the percentage of oxygen in the inspired air and a period of 10–20 min was allowed at a given level of oxygen before simultaneous blood samples were drawn from the umbilical and uterine vessels for $p\mathrm{O}_2$ analysis. In the ewes, maternal arterial $p\mathrm{O}_2$ was monitored continuously while in the mares the $p\mathrm{O}_2$ in individual samples was measured every 5–10 min. Blood $p\mathrm{CO}_2$ and $p\mathrm{H}$ levels were also determined during these experiments. The methods for measurement of $p\mathrm{O}_2$, $p\mathrm{CO}_2$ and $p\mathrm{H}$ have been described previously[2].

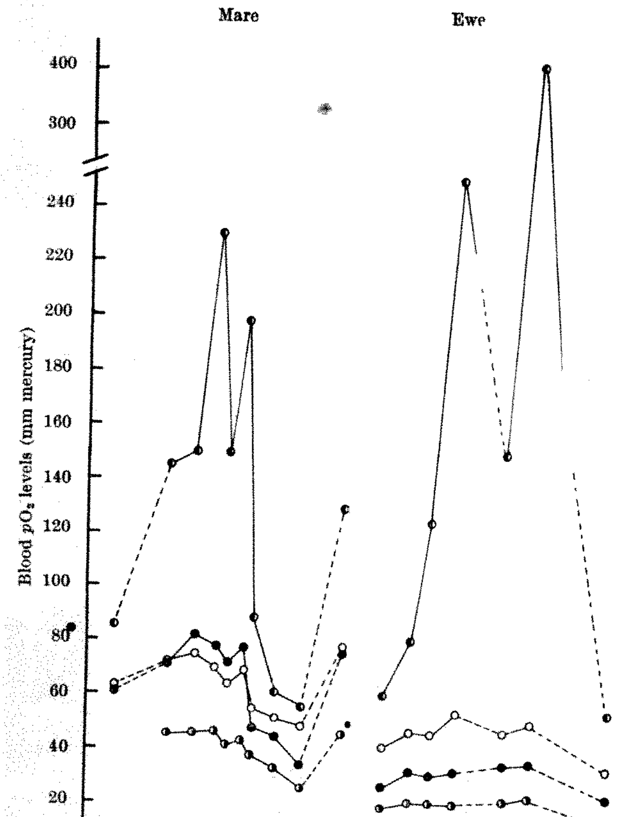

Fig. 1. The changes in $p\mathrm{O}_2$ in the umbilical vein (●), umbilical artery (◐) and uterine vein (○) at different levels of maternal arterial $p\mathrm{O}_2$ (◑) in the mare and the ewe. Each point shows the $p\mathrm{O}_2$ attained in the umbilical and uterine vessels after a period of 10–20 min at a given level of maternal oxygen intake.

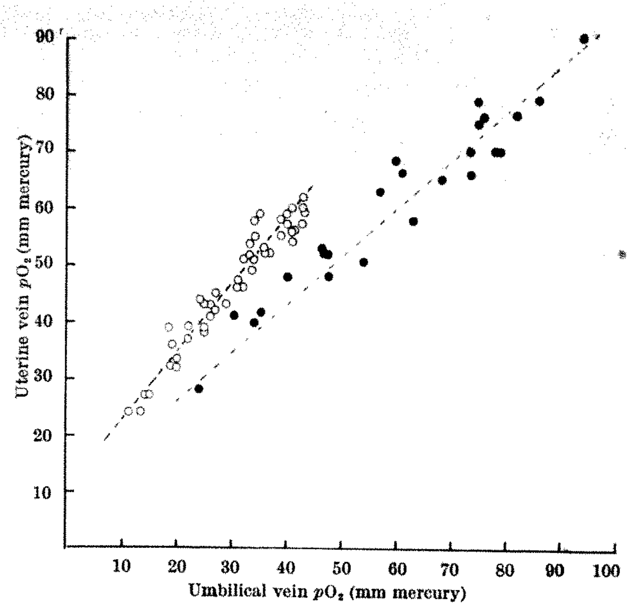

Fig. 2. The relation between the $p\mathrm{O}_2$ in the umbilical and uterine veins in the mare (●) and ewe (○). The values were obtained at maternal arterial $p\mathrm{O}_2$ levels ranging from 30–400 mm of mercury in the ewe (six animals) and 46–230 mm of mercury in the mare (four animals). Regression lines were fitted by the method of least squares – – – – ; the difference between the two regression coefficients $b = 1{\cdot}15 \pm 0{\cdot}036$ (ewes) and $b = 0{\cdot}80 \pm 0{\cdot}054$ (mares) is highly significant ($P < 0{\cdot}001$).

A marked difference between the mare and the ewe was evident even at normal maternal arterial $p\mathrm{O}_2$ levels (80–110 mm of mercury). In the sheep, the mean level for uterine vein $p\mathrm{O}_2$ was $50{\cdot}3 \pm 1{\cdot}63$ mm of mercury and the corresponding figure for the umbilical vein is $33{\cdot}9 \pm 1{\cdot}27$ mm of mercury ($n = 12$); these values were almost identical with those obtained in conscious ewes with indwelling catheters (our unpublished observations). In the mare, on the other hand, the $p\mathrm{O}_2$ levels in the two vessels were very similar (uterine vein: $61{\cdot}3 \pm 2{\cdot}94$ mm of mercury; umbilical vein: $57{\cdot}4 \pm 3{\cdot}26$ mm of mercury ($n = 7$)) and were far higher than any found in the ruminant. The contrast between these two species was enhanced when the effects of changes in maternal oxygenation were compared. The results from two such experiments are given in Fig. 1 and show the extent of the $p\mathrm{O}_2$ changes in the placental vessels when the maternal arterial $p\mathrm{O}_2$ is altered. In the sheep the changes in uterine and umbilical vein $p\mathrm{O}_2$ were very small compared with those in maternal arterial $p\mathrm{O}_2$, whereas in the mare umbilical vein $p\mathrm{O}_2$ exceeded that in the uterine vein when maternal arterial $p\mathrm{O}_2$ is high and the reverse occurred during maternal hypoxia. Thus the uniform gradient between the umbilical and uterine veins in the ewe[3] does not seem to be present in the mare. This is further illustrated in Fig. 2 in which the data from all experiments have been plotted to show the relation between umbilical and uterine vein $p\mathrm{O}_2$ in both species over a wide range of values.

There seems little doubt, even without the aid of statistics, that the slopes and positions of the two curves are very different. The results for the ewes were remarkably uniform with no values higher than 45 mm of mercury for the umbilical vein nor higher than 62 mm of mercury for the uterine vein, despite the fact that some of the ewes breathed 100 per cent oxygen for 0·5–1 h. In the mare the range of values was much greater because the pO_2 levels in both umbilical and uterine veins followed the different levels of maternal arterial oxygenation more closely. The difference between the slopes of the two regression lines, fitted by the method of least squares, was highly significant ($P < 0{\cdot}001$). That for the ewes was slightly greater than 1 ($b = 1{\cdot}15 \pm 0{\cdot}036$); thus the pO_2 difference between the umbilical and uterine veins was lowest (13 mm of mercury) at hypoxic levels and highest (18 mm of mercury) as the pO_2 in each became maximal. The data for the mares fitted a line with a slope of less than 1 ($b = 0{\cdot}80 \pm 0{\cdot}054$), so that in this species the pO_2 gradient between the two vessels decreased as pO_2 rose; at high levels the uterine vein pO_2 was less than that of the umbilical vein and the point at which the pO_2 in the two vessels was equal was 60 mm of mercury.

The very large and relatively unchanging gradient in pO_2 between foetal and maternal vessels in the sheep has been ascribed to the relative impermeability of the tissues (five to six layers) which separate the foetal and maternal blood[1,7], to the high degree of oxygen consumption by the placenta itself[3] and also to the possibility of shunts within the foetal umbilical circulation[3,7]. Such explanations, however, might equally well apply to the equine placenta, where six layers also separate the foetal and maternal blood, and there is no reason to suppose that oxygen is not used by this tissue to the same extent as in the ewe. Yet, in the mare, blood leaving the placenta on the foetal side is virtually in equilibrium with that leaving it on the maternal side. A relatively simple anatomical explanation for the apparent difference in oxygen transfer in the two species has recently been advanced by Steven[8]. He found that the maternal capillary networks which supply the areas of placental exchange are arranged very differently in the two species. Those of the mare are small networks supplied solely by maternal arteries, whereas those of the ewe are large and their extensive arterial blood supply is diluted to a varying degree with capillary blood which has already undergone some degree of exchange, so that most foetal villi in the sheep would seem to be exposed to a lower maternal pO_2 than those of the mare. The low and relatively constant umbilical venous oxygen pressure of the foetal lamb and the higher, more variable level in the foetal foal may therefore each reflect their particular maternal vascular arrangement.

We thank Dr A. V. Edwards and Dr J. C. D. Hickson for their help with the anaesthesia and preparation of the mares. This work was supported by a grant from the Horse Race Betting Levy Board.

Effects of Noradrenaline and Adrenaline on Oxygen Consumption Rate and Arterial Blood Pressure in the Newborn Pig

Moore and Underwood[1] showed that subcutaneous injection of noradrenaline in the newborn kitten produced a marked increase in metabolic rate, whereas adrenaline in the same dose was relatively inactive. A similar stimulation of metabolism in the newborn animal after the injection of noradrenaline was observed in the rabbit and rat[2] and in the human infant[3]. Subsequent work on the newborn rabbit showed the probable relation between the effect of noradrenaline and the activity of brown fat. Local heat production in brown fat is increased by the infusion of noradrenaline[4]. When the brown fat is excised, the rise in oxygen consumption during infusion is greatly reduced[5]. These observations suggested that the effect of noradrenaline should be investigated in the newborn pig, which seems to have no brown fat, and only about 1 per cent total fat in the body at birth[6]. The amount increases rapidly to reach about 10 per cent at 1 week of age[7].

Observations were made on male and female Large White piglets. The animals used were 1–23 days old and had body weights of 1·16–4·45 kg.

The rate of oxygen consumption was measured on conscious animals resting individually in a chamber of about 45 l. capacity. The chamber was situated in a controlled temperature room, which was kept at 30° C for experiments on animals less than 1 week old, and at 27° C for the older animals. The internal chamber temperature was approximately 1° C higher, so that the pigs were resting at about 2° C below their critical temperatures, which would be 33°–34° C for the newborn animals and about 30° C for the older ones. Rectal temperatures were maintained between 38·5° and 39·5° C. The rate of oxygen consumption was determined in the open circuit system using a Noyons diaferometer (Kipp and Zonen, Holland). The resting rate was measured for 0·5–1 h in the conscious animals. Then either adrenaline or noradrenaline was injected subcutaneously in a dose of 600 μg of amine base (0·1 per cent solution in 0·9 per cent saline)/kg body weight. The rate of oxygen consumption was determined again during a period of at least 1 h. At least 2 h were allowed to elapse before the second amine was injected, to allow time for the oxygen consumption rate to return to the original level. The effect of either drug on oxygen consumption could then be assessed on a preceding control period.

Fig. 1 shows that adrenaline produces an increase in oxygen consumption from the first day after birth, and that the effect persists in the older animals. Noradrenaline has no effect during the first week, and a relatively small effect in the second week.

The solutions of the amines were acid (pH $\simeq$ 4), and so sodium chloride solution brought to comparable acidity with hydrochloric acid, but devoid of amines, was injected into some pigs; there was no consistent effect on oxygen consumption rate. Injections of normal saline at pH 7 had no effect on oxygen consumption.

Arterial blood pressure responses were measured on a mercury manometer connected to a carotid artery cannula, in pigs anaesthetized with sodium pentobarbital administered intraperitoneally (40 mg/kg). For these measurements, the animal was partially immersed in a water bath held at 35° C and rectal temperature was maintained at 37°–38° C. The femoral vein was cannulated for injection of the drug. Doses of adrenaline and noradrenaline base, ranging between 0·1 and 0·5 μg/kg, were injected rapidly in volumes of 0·2 ml. of normal saline into the femoral vein. The effect on the response to amines of a beta-blocker, pronethalol, was determined in four pigs.

During the first 2 weeks after birth, the arterial blood pressure in anaesthetized pigs was found to be between 60 and 70 mm of mercury. The level in pigs at 3 weeks of age was about 100 mm of mercury. Fig. 2 shows that the pressor effect of noradrenaline was always greater than that of adrenaline during the first 3 weeks, a result opposite to the relative effects of the amines on oxygen consumption. Pronethalol, a beta blocking agent, had no effect on the response of blood pressure to noradrenaline, but it apparently potentiated the response to adrenaline. This is to be expected because if pronethalol blocked β-receptors, which are normally depressor, it would convert adrenaline from a mixed pressor/depressor to a pressor agent which would act, like noradrenaline, only on α-receptors.

In the conditions of these experiments, noradrenaline does not stimulate the metabolic rate in the newborn pig, although an effect appears after the first post-natal week. Adrenaline, however, has an effect which is apparent from birth. In this respect the pig is different from some other species and the difference might be related to the pig's lack of body fat in the immediate post-natal period. This possibility is supported by the increased metabolic rate produced by noradrenaline at 8 days of age, by which time the pig has formed a considerable amount of body fat. The results suggest that the mediation of noradrenaline cannot be invoked to explain any part of the vigorous metabolic response to cold of newborn pig. But the release of adrenaline could be very important for this response. The newborn pig relies principally on carbohydrate metabolism for energy production[8].

Responses to noradrenaline and adrenaline in newborn pigs bear comparison with those observed in newly hatched chicks[9]. In the chick, noradrenaline (300 μg/kg) causes a slight increase in oxygen consumption after hatching, but has little or no effect 1–3 weeks later. A similar dose of adrenaline results in a 30 per cent increase in metabolic rate in 1 day old chicks, an effect which remains demonstrable 1–3 weeks later. No brown fat has been found in the chick, and it appears that the chick, like the newborn pig, uses carbohydrate in producing the rise in metabolic rate which takes place in response to a cold environment.

The arterial blood pressure of 3 week old pigs has been found to be considerably greater than that observed during the first week. Both noradrenaline and adrenaline produce marked pressor responses during this period, the effect of noradrenaline always being larger than that caused by a similar dose of adrenaline. These findings are comparable with those reported in kittens[10] and in newborn rabbits[11].

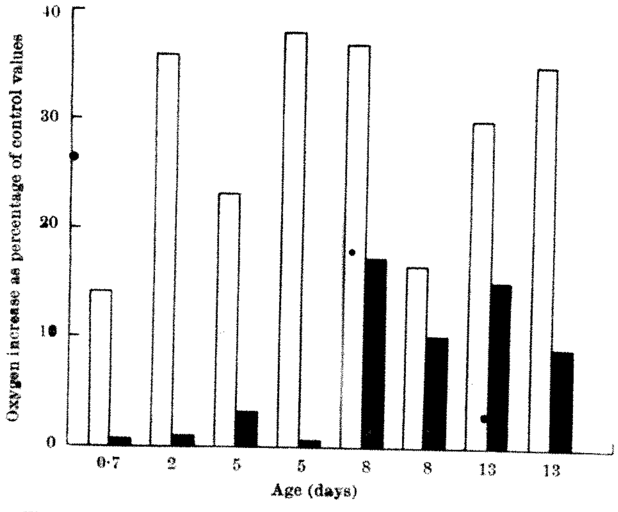

Fig. 1. The effects of 600 μg/kg of adrenaline (□) or noradrenaline (■), given subcutaneously, on oxygen consumption rate in pigs up to 13 days of age.

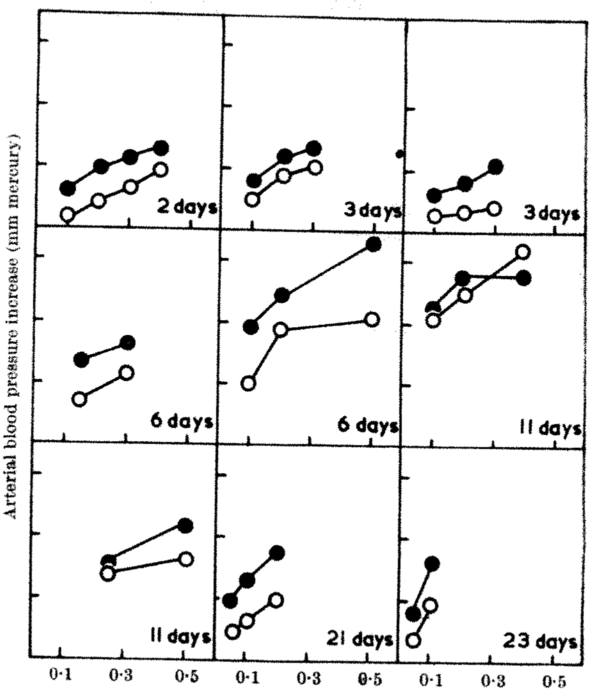

Fig. 2. The effects of adrenaline (○) and noradrenaline (●) given intravenously on arterial blood pressure in anaesthetized pigs up to 23 days of age.

Variations between species in the relative magnitude of the effects of noradrenaline and adrenaline on metabolic rate do not exist in their effects on arterial blood pressure. In the newborn pig, noradrenaline acts powerfully on the cardiovascular system, so that its lack of metabolic effect cannot be attributed to inactivation by enzymes, for example. The metabolic effect of noradrenaline, unlike that of adrenaline, may depend on the presence of brown fat. In its absence noradrenaline will, on this view, have no effect on metabolic rate.

Respiration in Myocardium

The qO_2 or oxygen uptake of a tissue is considered to be a reflexion of the metabolic energy produced through substrate catabolism to support its functional activities. It is usually accepted that the total *in vivo* oxygen consumption is directly related to ATP production as the

Table 1. OXYGEN CONSUMPTION OF THE ARRESTED RAT HEART
(ml. of O_2/min/g dry weight)

Experiment	Control	Oligomycin (5 μg/ml.) +	Cyanide (2·5 mmolar) +	Epinephrine (0·1 μg/ml.) +	Octanoate (2·5 mmolar)	*n*
1	0·136 ± 0·006 →	→	0·032 ± 0·003			6
2		0·128 ± 0·003 →	0·026 ± 0·002			6
3			0·034 ± 0·006 →	0·039 ± 0·008		6
4			0·022 ± 0·004 →	→	0·028 ± 0·002	6

Hearts were perfused with buffer containing 16 mmolar potassium with the additions shown. After 10–15 min, the qO_2 was determined and the second condition was applied to the same heart with a second determination of qO_2 after 10 min. Results are expressed as the mean ± *S.E.M.*

sole energy transfer and storage mechanism for endergonic processes[1]. Energy balance calculations in biology make use of this assumption, which is based on the known *in vitro* efficiencies of these processes. Recently biochemists have shown that certain non-mitochondrial enzyme systems assimilate or "take up" oxygen[2] and that respiration without phosphorylation is probably essential to many of the biological functions of mitochondria[3]. The relative contribution of non-phosphorylating and non-mitochondrial oxygen uptake to total respiration *in vivo* has been studied in the isolated perfused rat heart. Oligomycin and cyanide were used as inhibitors to distinguish mitochondrial but non-phosphorylating respiration from non-mitochondrial respiration.

Hearts were removed from 250 g white male Wistar rats (fed *ad libitum*) and perfused as described previously[4-6]. To eliminate "mechanical" contributions to qO_2 in studies of the basal "metabolic" qO_2, 16 mmolar potassium was used for cardiac arrest[6]. Oxygen consumption (ml. of O_2/min/g dry weight) was calculated from the arteriovenous pO_2 difference determined in an oxygen electrode. All determinations were made after stabilization for 10 min at the beginning of perfusion and 10 min after experimental intervention. In this preparation 2·5 mmolar sodium cyanide provided maximal qO_2 inhibition and oligomycin (5 μg/ml.) was used to inhibit oxidative phosphorylation[6].

Though the oxygen consumption of the rat heart *in vivo* is not known, an extrapolation might be made from *in vitro* perfusion systems in which pressure and/or volume work are performed. Values equivalent to 1·0 ml. of O_2/min/g dry weight have been obtained by Dr Howard E. Morgan (personal communication) and Dr Lionel Opie[7]. This value was selected as an estimate of the qO_2 of the working heart. The Langendorff heart preparation I used beats without performance of external work, and decreased the value to 0·5 ml. of O_2/min/g dry weight[4-6]. When all mechanical activity was eliminated by potassium arrest, the qO_2 fell to approximately 0·15 ml. of O_2/min/g dry weight, the basal "metabolic" oxygen consumption of rat heart[5,6] (Table 1).

Eighty-five per cent of *in vivo* respiration in muscle is related to mechanical functions, which are supported by ATP, and an equally high portion of respiration must result in the production of high energy phosphate. Oligomycin is a potent inhibitor of oxidative phosphorylation in isolated mitochondria; any other respiration is not linked in an obligatory fashion to phosphorylation[8,9]. The effects in intact myocardium are analogous to those in mitochondria because there is a decrease in ATP (ref. 6), an inhibition of phosphorus-32 incorporation into ATP and an increase in DPNH fluorescence[10].

The dependence of the mechanical activities of myocardium on ATP has been demonstrated by a rapid arrest and decrease in ATP and qO_2 on exposure to oligomycin[6]. The greater portion of the arrested or basal qO_2 was not inhibited by oligomycin (Table 1)[6,10]. Non-phosphorylating respiration accounts for 85–90 per cent of the basal qO_2 (ref. 10). If the absolute value is constant, it could account for about 13 per cent of *in vivo* myocardial respiration. In fat cells, not dependent on ATP production to support mechanical activity, the portion of respiration insensitive to oligomycin was found to be 45 per cent (unpublished results from this laboratory). Though the energy produced is not stored as high energy phosphorus and might be considered as "waste", the high energy intermediates generated[3] may donate their energy to cellular processes capable of using it[3,11-16]. The efficiency or "coupling" of such an energy supply is not known but may be significant in certain pathological states[17].

The reduction of oxygen by mitochondria, whether or not it is accompanied by phosphorylation, may not be the only mechanism in the intact cell. Microsomes are capable of oxygen utilization and in isolated systems have the kinetic ability to accommodate rates of electron flow equivalent to those of mitochondria[2]. This is respiration unaccompanied by ATP formation and would be classified as a part of oligomycin-insensitive respiration of the intact cell.

Cyanide, an inhibitor of mitochondrial cytochrome oxidase, can be used to eliminate the oxygen uptake associated with mitochondrial activity. A definition of the respiration remaining in the intact heart is therefore "non-mitochondrial", but not necessarily microsomal. I found a remaining respiration of 0·022 ± 0·004 to 0·036 ± 0·006 ml. of O_2/min/g dry weight in the presence of cyanide (Table 1). This accounts for only 3 per cent of the total qO_2 of the working heart but approximately 20 per cent of the resting or the oligomycin-insensitive respiration (0·026 of 0·128, Table 1). Approximately 20 per cent of respiration of perfused rat liver, another system without the ATP requirement of contractile function, has been similarly defined as non-mitochondrial[18]. Epinephrine and octanoate, which increase the level of non-phosphorylating respiration in the rat heart[6,10], did not change the qO_2 in the presence of cyanide (Table 1); their effect is most likely to stimulate mitochondrial non-phosphorylating respiration.

The heart uses 87 per cent of its respiratory activity for ATP production, 85 per cent being directly related to contractility. The remaining oxygen uptake is associated with non-phosphorylating mitochondrial and microsomal activities the nature, stoichiometry and efficiency of which are not clear.

Reduction of Response Time for Potential in Salt Bridge Reference Electrodes for Electrophysiology

SATURATED or 3 molar potassium chloride salt bridges connected to a calomel half cell or a silver–silver chloride electrode are used extensively in electrochemistry and electrophysiology as reference electrodes for potential measurements. The 3 molar potassium chloride salt bridge electrode is used in electrophysiology primarily because the liquid junction potential from the salt bridge to physiological solutions is only a few millivolts and varies little at equilibrium when in different physiological solutions. Derivations for this liquid junction potential have been obtained[1-3].

The equilibration time for potentials in salt bridge reference electrodes is particularly important in electrophysiological studies where the dependence of the cell membrane potential on various ions is being measured. With cylindrical salt bridge reference electrodes (Fig. 1*a*) it has been found that long-lasting transient potentials of several millivolts can occur in certain situations when substitutions or changes are made in the physiological saline. In experiments where the membrane potential of crayfish axons in physiological saline was being measured, the transient change in potential at the 3 molar potassium chloride salt bridge reference electrode amounted to almost 4 mV when external chloride was changed from 240 to 130 mmolar[4]. The chloride was changed by one to one substitution with glucuronate or propionate. This potential artefact is considerable because it is measured electrically in series with the potential change of the cell membrane, which itself is usually only a few millivolts. The elimination and understanding of this transient error in potential in reference electrodes is therefore important in electrophysiology.

The transient potential change at the reference salt bridge electrode arises from the following factors. The concentrations in a cylindrical salt bridge, or any other salt bridge where diffusion is in one dimension, never acquire a steady state distribution. After a long equilibration time of a 3 molar potassium chloride-filled salt bridge in one solution, the concentrations at the cylinder tip approach that of the external solution and the concentrations approach the initial 3 molar potassium chloride concentration only a considerable distance into the cylinder. Consequently, with a change in the external solution, two liquid junction potentials appear. The first is the original liquid junction potential which is distributed over the extended boundary between the first external solution and the 3 molar potassium chloride in the cylinder. The second liquid junction potential is at the cylinder tip between the new solution outside and the first solution trapped or still held in the cylinder. The response time of the salt bridge reference electrode is the overall diffusion time necessary for a single liquid junction potential to be produced. This can be hours. If there are large liquid junction potentials between exchanged external solutions, large transient potential artefacts appear. This artefact arises as a consequence of one dimensional diffusion in the cylindrical salt bridge, so the diameter of the cylinder is not important in the response time.

One solution to this problem has been to use a flowing 3 molar potassium chloride junction[5]. This approach is usually impractical for physiological studies where solutions must often be retained and any leakage of potassium into the external saline would cause undesired physiological effects. Another approach would be to use a reference electrode the liquid junction of which consists of a small hole in a thin impermeable membrane which separates a large volume of 3 molar potassium chloride (in agar to prevent bulk fluid flow) and the physiological saline. The response time for voltage at the reference electrode would then depend on the time required for a steady state ion distribution to appear across this thin hole. Another successful method is to use a conical reference electrode of small tip diameter and large solid angle taper[4] (Fig. 1*b*).

The development described here is of the perforated membrane salt bridge reference electrode (Fig. 1*c*). This electrode consists of a large cylinder with an impermeable thin plastic membrane (0·001 cm thick, polyvinylidine chloride, polyester, polyethylene, etc.) glued with epoxy cement to one end. A small hole, about 0·02 cm in diameter, is made by puncturing the centre of the membrane with a small insect pin (No. 00) heated by attaching it to an electric soldering iron. The electrode is filled with 3 molar potassium chloride and 3 per cent agar to prevent fluid flow. A silver–silver chloride electrode or calomel cell is then connected to the 3 molar potassium chloride in the cylinder which completes the reference electrode. When immersed in crayfish saline, the electrical impedance of this perforated membrane electrode (with silver–silver chloride connexion) has been less than 750 ohms, which is satisfactory for grounding most physiological solutions. Fig. 1 shows a comparison of the response times of potential for a cylindrical, conical and a perforated membrane salt bridge reference electrode when external chloride is changed. The time for 90 per cent response (measured to final steady state potential) for the perforated membrane electrode has been faster than 0·5 sec and may be faster because the measurement was limited by the time necessary to change solutions and the response time of the silver–silver chloride electrode. The conical reference electrode performed almost as rapidly as the perforated membrane electrode. But the cylindrical reference electrode did not acquire a steady state potential even after many minutes. Voltage readings with cylindrical reference electrodes are therefore much less reliable in situations where there are changing physio-

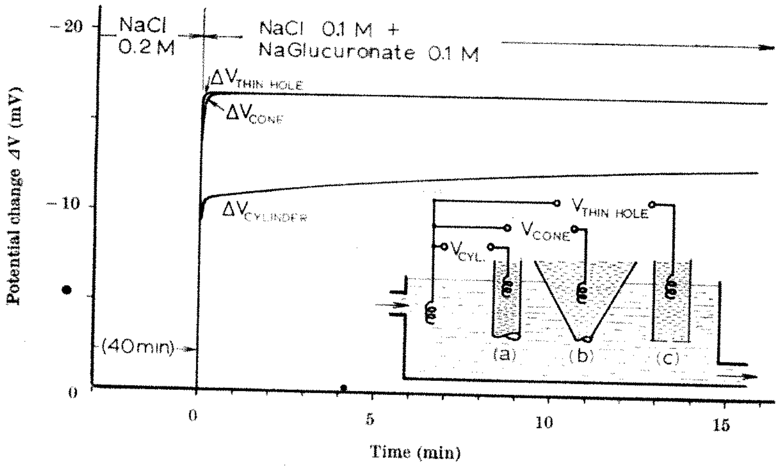

Fig. 1. The time course of potential for a cylindrical, conical and a perforated membrane salt bridge reference electrode referred to an Ag–AgCl electrode. The electrodes were placed in 0·2 molar NaCl for 40 min before the solution was suddenly changed ($t = 0$) to 0·1 molar NaCl and 0·1 molar Na glucuronate in order to change chloride from 0·2 to 0·1 molar without changing total concentrations or activity coefficients. The conical and perforated membrane electrodes became rapidly stable in potential within several seconds. Even after 15 min the cylindrical electrode had not acquired a steady state. The cylindrical salt bridge electrode was 0·1 cm in diameter. Cylinder diameter was unimportant in these comparisons. The conical salt bridge electrode has a 0·02 cm tip diameter and the taper subtended an angle of 40° until the diameter reached 0·2 cm, after which the electrode was cylindrical. The perforated membrane electrode consisted of a 0·5 cm diameter cylinder covered with a 0·001 cm polyester membrane ('Mylar', 'Dacron', 'Terylene') with a 0·02 cm diameter hole. All electrodes were filled with 3 molar KCl and 3 per cent agar.

logical solutions. An effective increase in reliability is obtained with a small hole perforated membrane reference electrode.

Evoked Potentials reflecting Interocular and Monocular Suppression

It is well known that averaged visually evoked potentials (EPs) from the human occipital scalp show correlations with a number of subjective features of perception; but recent attempts to find EP correlates of the phenomenon of image suppression, as in interocular rivalry, seem to have yielded conflicting results[1–4]. In most of these experiments contrasting stimuli to the two eyes were allowed to set up spontaneously fluctuating rivalry, and the subject was required to press a key to indicate which stimulus was dominant at any time. There are, however, situations in which the perceptual dominance of one stimulus over another is stable. In the two experiments reported here, perceptual suppression of one stimulus by another in such stable situations has been found to be clearly accompanied by correlated changes in the averaged EPs.

The stimulus conditions used were dictated by an interest in a quite different phenomenon, and the discovery of EP correlates of image suppression was accidental. When a randomly patterned stimulus ("visual noise") is followed by a blank flash optically superimposed on the same area of the visual field, curious perceptual anomalies, and corresponding anomalies in the EP, occur at repetition rates of the order of 10–15/sec, which are not seen if the patterned and blank fields are presented to different eyes[5]. At lower rates of the order of 2/sec, these anomalies disappear; but two kinds of suppression phenomena are still observed.

(1) When the blank field, *B*, is flash-presented simultaneously to the same eye or eyes as the noise-patterned field, *N*, it suppresses perception of the patterned field, which becomes gradually visible as the number of milliseconds between *B* and *N* is increased. The critical interval depends on relative brightness, and in the present case was between 10 and 20 msec. This suppression of one stimulus by another presented to the same eye is termed "perceptual blanking".

(2) When *N* is presented to one eye and *B* to the other, perception of *B* is normally suppressed over a wide range of time intervals between *B* and *N*, and there are no perceptual effects of changing the timing or brightness of *B* over several tens of msec and several log units, respectively. This phenomenon is referred to as "interocular suppression".

In the present experiments, the EPs in response to single pairs of noise-patterned and blank stimuli presented approximately twice/sec, were recorded (by conventional averaging methods) with varying time intervals of the order of 0–50 msec between noise and blank, and with the two stimuli presented to either the same or different eyes. The two stimuli (*N* and *B*) were back-projected on separate screens and optically superimposed by means of a half silvered plane mirror, after optical polarization in orthogonal planes. Two pairs of polaroid spectacles were provided (fixed to the main framework, not worn) with polarizing orientations chosen to enable the two stimuli to be presented either (*a*) each to separate eyes or (*b*) both to the same eye or eyes at roughly half intensity.

Repetition intervals of about 0·5 sec were found long enough to prevent significant overlap between successive EPs, and the responses were averaged over runs of 60 to 105 presentations lasting from 0·5–1 min. Every run was repeated and the two results were superimposed on the cathode ray tube screen before photographing, to give an indication of their statistical significance. Two orthogonal bipolar recording placements were used, just to the left of the occipital midline, the lowest electrode being 1 cm left of the inion (Fig. 1).

Typical evoked responses to presentation of noise-patterned, *N*, and blank, *B*, flashes alone, at intervals of 573 msec, were recorded in the same subject on a separate occasion and are shown for reference in Fig. 1. *N* and *B* in this case were matched for subjective brightness (0·1 log ft. Lambert). Each trace is a superposition of the results of two successive runs of 105 responses each, indicating the run to run consistency obtainable. The upper of each pair of traces represents the average evoked potential, *L*, parallel to the midline; the lower represents the potential, *T*, transverse to it. It will be seen that although the longitudinal components are similar, the transverse components are strikingly different for patterned and blank stimulation; and the lowest pair, recorded 10 min later than the first but in the same conditions, indicates that this difference is also consistent. Its principal feature lies in the contrast between the rapid downward deflexion in response to "noise", and the slower upward deflexion at the same latency in response to "blank". These records were taken with binocular view and without polaroid, to give maximum signal to noise ratio. They have been found to be repeatable at any time in the same subject. Although bipolar, they reveal a similar contrast to that observed by Rietveld *et al.*[6] between the monopolar responses to checker-patterned and blank fields.

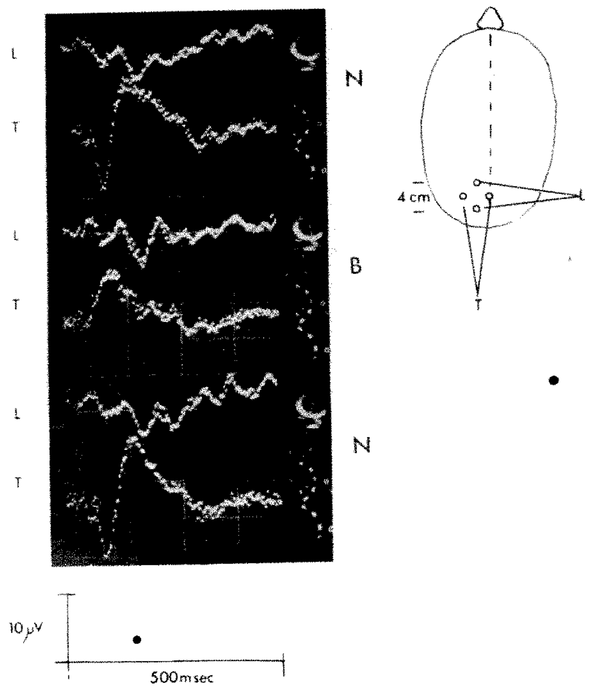

Fig. 1. Typical averaged responses to 105 exposures of noise-patterned, *N*, and blank, *B*, stimuli. Bipolar potentials recorded, *L*, parallel, *T*, transverse to midline. Each trace shows the results of two successive runs superimposed to indicate run-to-run consistency. Repeatability of *N* responses after an interval of 10 min may be checked by comparing upper and lower *N* records.

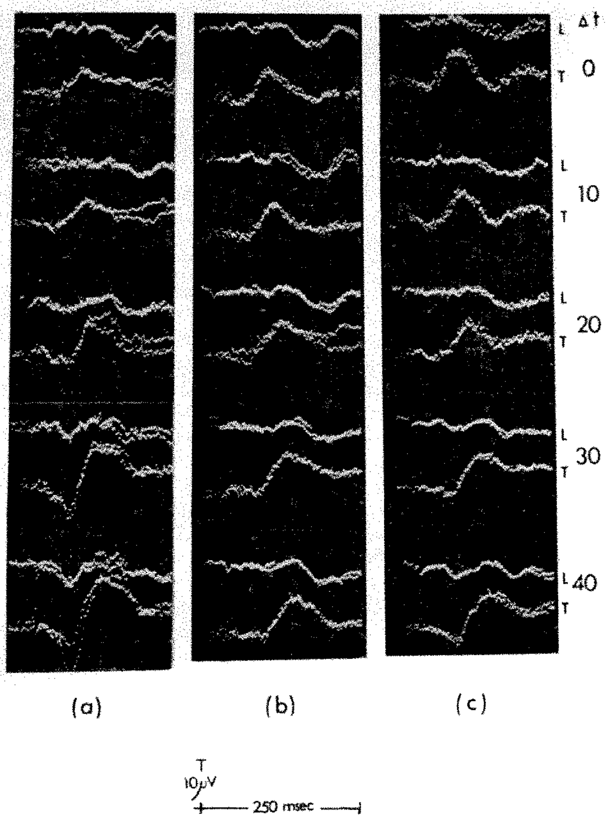

Fig. 2. *a*, Effects of increasing time interval, Δt, between N and B during normal binocular viewing. Note change of time-scale from Fig. 1. Each trace shows two successive results superposed. *b* and *c*, The same for left-eye and right-eye viewing, respectively.

Figs. 2*a*–*c* show the effect on the evoked potentials of increasing the time interval, Δt, between noise-patterned and blank flashes during normal binocular and monocular viewing. A repetition interval of 473 msec was used, and the blank flashes were adjusted to be subjectively 0·7 log units brighter than the noise. At low values of Δt, the transverse EP in all three cases shows the typical upward response to B (compare Fig. 1 B noting the difference in time scale), and the subject reports masking of the noise pattern. As Δt increases above 20 msec, the noise pattern becomes progressively more visible subjectively, and the EP correspondingly shows the initial downward deflexion (compare Fig. 1 N) evoked by N. With monocular viewing (Figs. 2*b* and *c*) the downward deflexions are much less pronounced, but the general trend (especially with right-eye viewing) is similar.

When the noise-patterned field is flashed to one eye and the blank to the other, suppression caused by interocular rivalry is observed, with the opposite effect; the blank field is rendered invisible by the noise-patterned field. The corresponding changes in the transverse EP are illustrated in Fig. 3. The longitudinal component, as before, showed no significant changes and has been omitted for clarity.

The first two rows show typical responses to N and B, respectively in left, L, or right, R, eyes, with $\Delta t = 0$, 30, 90 msec. The third row shows clearly how simultaneous presentation of N and B to opposite eyes gives the downward deflexion characteristic of N, with suppression of the upward "B" deflexion. With binocular viewing of N and B together, the responses in the fourth row of Fig. 3 were obtained, as in Fig. 2.

The contrast between third and fourth rows shows that a noise flash in one eye renders the transverse EP insensitive to the timing as well as the brightness of a blank flash in the other. With normal binocular viewing of N and B, blanking of the downward "N" component can be seen at $\Delta t = 0$, when the N stimulus is perceptually "blanked" by B, but not at $\Delta t = 30$ and 90 msec, when both stimuli are seen. The upward "B" component is present throughout. With dichoptic viewing of the same stimuli (third row), the downward "N" response is present at all values of Δt, the form of the EP shows no trace of the "B" response, and there is no significant change with Δt. This tallies with subjective experience, which is also quite insensitive to the brightness or timing of B in one eye (over this range) provided that N is presented only to the other eye.

These results seem to give definite evidence of EP changes correlated with two kinds of subjective suppression of one stimulus by another. Their detailed implications will be discussed elsewhere, but they suggest that whatever switching mechanisms are involved in the perceptual blanking and the interocular suppression

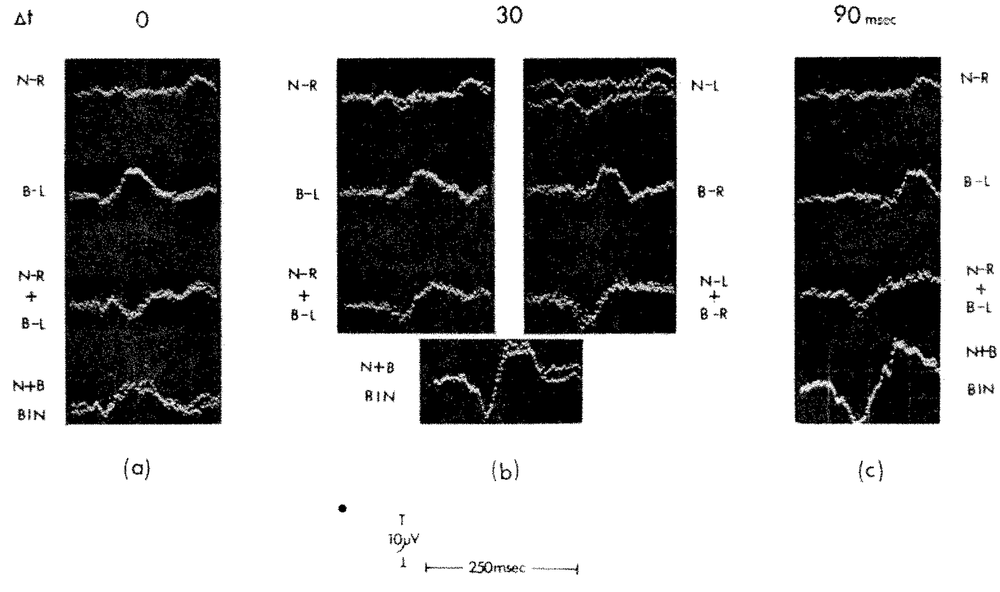

Fig. 3. Comparison of monocular (first two rows), dichoptic (third row) and binocular (fourth row) conditions: *a*, with $\Delta t = 0$; *b*, with $\Delta t = 30$ msec; *c*, with $\Delta t = 90$ msec. Note clear suppression of upward "B" response with dichoptic but not with binocular viewing. L = Left eye, R = right eye, N = noise, B = blank. Each picture shows two successive results superposed.

observed, they lie peripheral to the origin of the pattern-specific component of the EP. It is interesting to note that combination of the EPs to blank and noise is approximately linear when both stimuli are applied to the same retina, with a relative time interval of 30 msec or above. As this was also the condition in which both stimuli were subjectively visible, it suggests that the cerebral EP generating mechanisms activated by blank and patterned stimuli are largely independent. This would be expected if patterned stimulation excites in man a cortical population which is specifically contour-sensitive, analogous to those found in cat and monkey[7]. It might also explain some of the negative findings by other investigators using patternless fields.

These results may have some bearing on the recent finding by Lehmann and Fender[8] that the average EP to a blank flash was reduced according to the amount of structure presented (steadily, not flashed) to the other eye. They report that "spontaneous fading" occurred, but rely on earlier negative findings to discount its effect on the EP. If, however, what they observed occasionally with a steady pattern was the kind of interocular suppression that happens predictably with a flashed pattern, nothing more might be needed to explain a reduction in the average EP.

The reported lack of correlation between EPs and the fading of stabilized retinal images[9] would not discount this possibility, unless such fading were known to depend on the same mechanism as interocular suppression. The perceptual differences between the two phenomena make this unlikely.

Antagonism of Presynaptic Inhibition in the Cuneate Nucleus by Picrotoxin

AN afferent volley in a cutaneous forelimb nerve produces on the surface of the cuneate nucleus a characteristic electrical response. This consists of a brief initial spike potential indicating the arrival of the primary afferent volley, followed by a negative wave (N wave) lasting about 4–5 msec and a prolonged positivity (P wave) reaching a maximum in 20–30 msec and lasting for about 200 msec[1]. Similarly, N and P waves result from electrical stimulation of the contralateral sensorimotor cortex[2]. The N wave produced by the afferent stimulus is thought to be caused by synaptically induced depolarization of the cuneate cells by the ascending volley in the dorsal column[3]. Systematic investigation of the P waves produced by cutaneous volleys and by cortical stimulation led Andersen *et al.*[3] to suggest that both are caused by prolonged depolarization of cuneate tract fibres close to their synaptic terminals in the cuneate nucleus. This suggestion was further supported by excitability testing of these presynaptic fibres at their terminals and along their length, and by intracellular recording from these fibres[4]. With the technique of extracellular single cell recording, Jabbur and Towe[5-8] had shown earlier that the sensorimotor cortex (primarily the contralateral) produced excitatory and inhibitory influences on cuneate and gracile neurones. With the additional technique of antidromic activation of dorsal column neurones after medial lemniscal stimulation[9,10], two types of neurones have been identified. These are direct projection neurones, or dorsal column-thalamic relay neurones, which are depressed by antecedent descending volleys from the sensorimotor cortex, and interneurones, through which the cortex exerts presynaptic (and sometimes post-synaptic[11]) inhibition on the afferent inflow passing through the dorsal column nuclei. There is histological evidence for the presence of these corticofugal projections[12].

Presynaptic inhibition has been reported to be reduced by the convulsive drug picrotoxin in doses which do not appreciably interfere with postsynaptic inhibition[13]. Strychnine, on the other hand, can block postsynaptic inhibition without altering presynaptic inhibition[13]. If the P wave produced in the cuneate nucleus by peripheral and by cortical stimulation is a reflexion of afferent terminal presynaptic depolarization, as proposed originally[3], then it would be expected to be sensitive to picrotoxin. Similarly, cortical inhibition of the response of cuneothalamic neurones to peripheral stimulation would be reduced by picrotoxin, if this inhibition were mediated, at least in part, presynaptically.

Cats were anaesthetized with α-chloralose (60 mg/kg) or pentobarbital sodium (36 mg/kg) and immobilized with a muscle relaxant (gallamine triethiodide or decamethonium bromide). The cuneate nucleus was exposed for recording gross potentials with a silver ball surface electrode placed about 3 mm below the obex where the largest N and P waves are usually recorded[3]. The contralateral sensorimotor cortex was also exposed and a pool of warm paraffin oil was made around it. Bipolar platinum electrodes were used to stimulate the forearm area of the pericruciate region. Stimulating needle electrodes were inserted into the ipsilateral forepaw. Above-threshold stimuli of 0·1 msec duration were applied peripherally, whereas a single pulse lasting 0·04–0·08 msec, or a train of four such pulses at a frequency of 312/sec, was applied to the cortex. A master unit drove both stimulating channels at 1 c.p.s. Typical responses to peripheral stimulation and to cortical stimulation are depicted in Fig. 1 *A*1 and *B*1, respectively.

The effects of 0·2–1·0 mg/kg of picrotoxin, administered intravenously, appeared within 4–5 min. Gradual reduction in the size of the P wave was observed, and in 10–20 min the higher doses resulted in almost complete disappearance of the P wave with little or no reduction in the size of the N wave. At the peak of action, the previously positive wave gave way to prolonged negative discharges. Both peripherally and cortically evoked P waves were depressed. Reduction in the size of the P wave could also be produced by local instillation of a few drops of 0·1 per cent picrotoxin on the surface of the cuneate nucleus (Fig. 1). All these changes could be effectively reversed by intravenous administration of small doses of pentobarbital sodium (10–15 mg/kg). Intravenous injection of 0·1 mg/kg of strychnine sulphate failed to depress the P wave; instead it frequently increased it in size. Preliminary experiments with single unit extracellular recording from cuneothalamic neurones indicate that inhibition by conditioning contralateral cortical stimulation can also be reduced by picrotoxin, whether administered intravenously or applied locally.

These results support the hypothesis that the P wave recorded in the cuneate nucleus, whether produced by

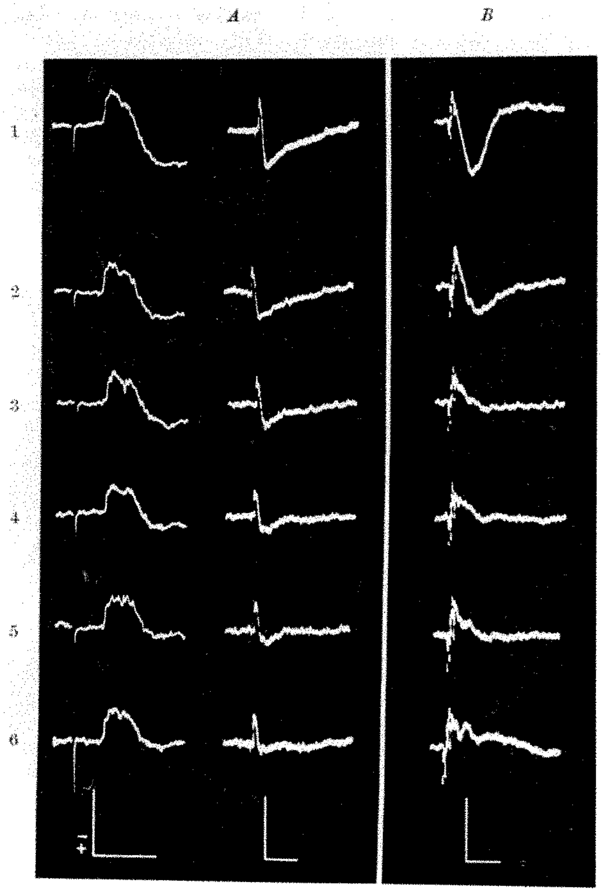

Fig. 1. The effect of local application of picrotoxin on cuneate responses. *A*, Cuneate potentials recorded after ipsilateral forepaw stimulation at two different sweep speeds, showing the *N* wave (left) and the *N* and *P* waves (right). *B*, Cuneate potentials recorded after a train of four pulses delivered to the forearm area of the contralateral sensorimotor cortex. (1) Control; (2–6) 5, 13, 22, 33 and 43 min after local application of a few drops of 0·1 per cent picrotoxin. Calibration: *A* (left), 200 μV and 10 msec.; *A* (right) and *B*, 200 μV and 50 msec.

cutaneous or by contralateral sensorimotor cortical stimulation, is indicative of dorsal column fibre depolarization or presynaptic inhibition.

Convulsant Action of Polyphenols

IN 1936 Bacq[1] demonstrated that, in addition to sensitizing certain smooth muscles of the cat to stimulation of sympathetic nerves and to injected adrenaline, some polyhydroxylic phenols also possessed convulsant activity. The sensitization was originally attributed to the antioxidant properties of the phenolic compounds. More recent studies, however, have indicated that polyphenols augment the peripheral actions of adrenaline by competitive inhibition of catechol-*O*-methyl transferase (COMT) (refs. 2–4). It has also been suggested that the central effects of polyphenols may be caused by a similar mechanism[5]. Our study was undertaken to investigate the possible role of adrenergic mechanisms in the central effects of these compounds.

Pyrogallol has been shown to be more potent than catechol as an inhibitor of cerebral COMT, both *in vitro*[6,7] and *in vivo*[8], and should therefore be a more powerful convulsive agent if COMT inhibition is involved in the central action of the hydroxy benzenes. The convulsant activities of catechol and pyrogallol, together with those of phenol and 2,3,4-trihydroxy acetophenone, were determined using female mice of an inbred strain, weighing 18–22 g. The compounds were injected intraperitoneally and the doses which induced convulsions in 50 per cent of the animals (CD_{50}) were determined using the method of Weil[9] with groups of ten mice.

The results (Table 1) show that pyrogallol and 2,3,4-trihydroxy acetophenone, substances reported to be among the most potent inhibitors of cerebral COMT (ref. 8), are much less active convulsants than catechol. In fact, the convulsions elicited by pyrogallol occurred only after a sustained period of depression and were always accompanied by distinct cyanosis, so the possibility that these were anoxic in origin cannot be excluded. Phenol, on the other hand, although not methylated by COMT (ref. 10), produced convulsions of rapid onset, which were very similar to those induced by catechol.

Table 1. CONVULSANT ACTIVITY OF CERTAIN PHENOLIC COMPOUNDS IN MICE

Compound	CD_{50} mmole/kg intraperitoneally (95% confidence limits)
Phenol	1·04 (0·93–1·17)
Catechol (1,2-dihydroxybenzene)	0·37 (0·35–0·41)
Pyrogallol (1,2,3-trihydroxybenzene)	5·71 (4·07–7·93)
2,3,4-trihydroxy acetophenone	> 8·0

Despite the fact that the *in vivo* inhibition of cerebral COMT by pyrogallol is well documented[8,11] it has been suggested that pyrogallol may not be able to pass the blood–brain barrier because the levels of catecholamine in the brain are altered by this compound only when it is administered intracerebrally[12]. Preliminary experiments in our laboratory, however, using a simple ferric chloride colorimetric reaction, have shown that pyrogallol injected intraperitoneally into mice readily enters the brain.

Further evidence to demonstrate the potent convulsant action of catechol in comparison with that of pyrogallol was obtained by applying the compounds directly to the spinal cord of frogs. Decerebrate frogs were anaesthetized with urethane (1·5 g/kg) to prevent spontaneous movements. Perfusion of the neuraxis was carried out by means of a needle inserted into the cord at the junction of the urostyle with the ninth vertebra and the electromyogram was recorded with needle electrodes inserted into the hypoglossal muscles. Results from one experiment are shown in Fig. 1.

The electromyogram showed no change in activity when the perfusate was changed from ordinary frog Ringer to Ringer containing pyrogallol (10 mg/ml., Fig. 1*a*) whereas a large increase in activity occurred when the perfusate contained catechol (10 mg/ml., Fig. 1*b*). Furthermore, in experiments using rats, it was found that when injected intracisternally, catechol (0·4 mg) elicited myoclonic twitches of the neck and ears whereas

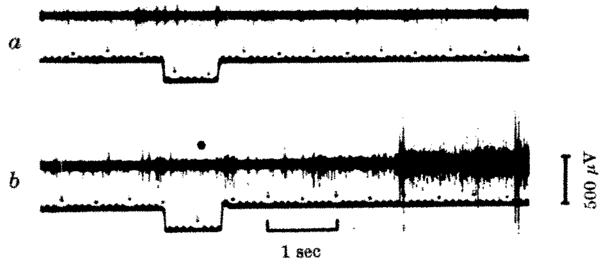

Fig. 1. Activity recorded from needle electrodes in the hypoglossal muscles of a decerebrated anaesthetized frog. A downward deflexion of the time scale indicates a change in the perfusing fluid from Ringer's solution to Ringer's solution containing 1,2,3-trihydroxybenzene (pyrogallol, 10 mg/ml.) in (*a*) and 1,2-dihydroxybenzene (catechol, 10 mg/ml.) in (*b*).

pyrogallol injected by this route had no effect in doses of up to 2·5 mg. Clearly, therefore, pyrogallol possesses little excitatory activity on the central nervous system when compared with catechol.

Further evidence that the central excitatory effects of catechol are unlikely to be the result of an adrenergic mechanism is given in Table 2. Reserpine in doses which deplete the brain of catecholamines[13] and chlorpromazine, a central adrenaline antagonist[14], both failed to antagonize the convulsive activity of catechol.

Table 2. EFFECT OF RESERPINE AND CHLORPROMAZINE ON CONVULSIONS IN MICE INDUCED BY CATECHOL

Pre-treatment			
Drug	Dose	Time administered prior to catechol	Catechol CD_{50} mmole/kg (95% confidence limits)
Saline		2 h	0·36 (0·32–0·41)
Reserpine	10 mg/kg	6 h	0·34 (0·31–0·38)
Chlorpromazine	20 mg/kg	2 h	0·37 (0·34–0·41)

In conclusion, therefore, the central effects of catechol and pyrogallol are unrelated to their relative activities as inhibitory agents of COMT and the convulsant activity of catechol is unlikely to be mediated by central adrenergic mechanisms. The mechanisms involved in the central excitatory actions of catechol and other polyhydroxic phenols are now being investigated.

New Glandular Structure in the Kidney of *Clarias batrachus* (Linn.)

DURING a study of the kidney and associated structures in Indian fishes, I have come across a peculiar feature, as yet undescribed, in the mesonephros of the air-breathing teleost, *Clarias batrachus* (Linn.). In this species a spheroidal multicellular gland is present inside the renal mass, adjacent to the extension of the caudal vein (Fig. 1). It is surrounded by a delicate investing membrane and is constituted by the close folding of the epithelial layer so as to form a number of semi-parallel ridges of columnar gland-cells separated by narrow interspaces. The chink-like lumen of the gland opens, by a minute orifice into a space surrounding it, and this periglandular space discharges, by a funnel-shaped aperture, into a duct situated on one side of the gland (Fig. 2).

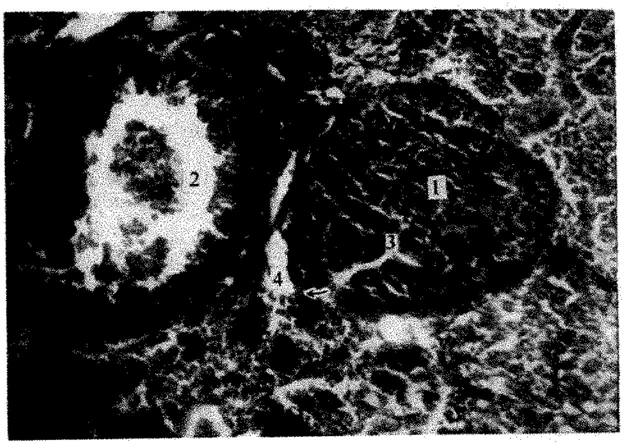

Fig. 1. Part of a transverse section of the mesonephros of *Clarias batrachus* showing its position inside the kidney. (× 900.) 1, Intra-mesonephric gland; 2, extension of the caudal vein inside the renal mass; 3, chink-like lumen of the intra-mesonephric gland; 4, periglandular space; the arrow indicates the opening of the intra-mesonephric gland into the periglandular space.

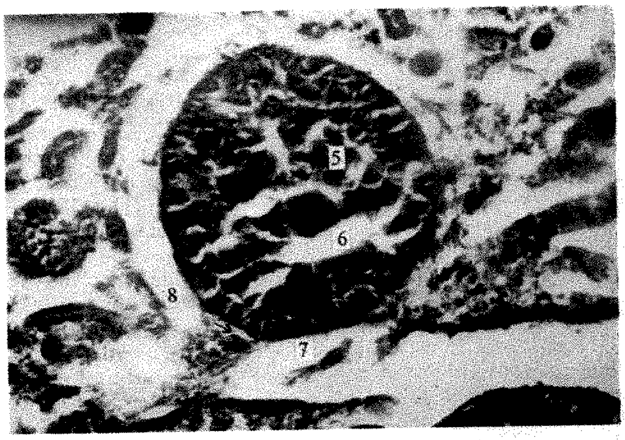

Fig. 2. Part of a transverse section of the mesonephros of *Clarias batrachus* showing the structure of the intra-mesonephric gland and the opening of the periglandular space into a duct. (× 900.) 5, One of the glandular ridges; 6, an interspace between the ridges; 7, a duct; 8, the periglandular space; the arrow shows the opening of the periglandular space into the duct.

It is evident from this description that the gland is a definitive structure. Its situation, disposition and histological details show that it is different from the adrenal inter-renal and other glands so far described in connexion with the kidney. It may be designated as the "intra-mesonephric gland". Further investigations particularly on its histochemistry and function are in progress.

Effect of Haemoglobin on Experimental Infections with *Pasteurella septica* and *Escherichia coli*

BOTH haematin hydrochloride and ferric ammonium citrate can abolish the protective effect of immune serum in experimental infections with *Pasteurella septica* in mice[1]. Ferric ammonium citrate has the same effect with *Clostridium welchii* Type *A* infections in guinea-pigs[2]. The importance of these observations depends on the fact that iron can abolish the bacteriostatic effect of sera against *Cl. welchii in vitro*[3]. Because iron compounds seem to have such similar effects both *in vitro* and *in vivo*, it seems quite likely that the bacteriostatic action of serum may play an important part in resistance to bacterial infections.

We find that homologous lysed red cells as well as heterologous crystalline haemoglobin are effective in abolishing passive immunity to *P. septica*. Homologous lysed red cells and crystalline haemoglobin also enhance the virulence of *Escherichia coli* (type 0111*B*4) in normal guinea-pigs.

Red cells were prepared from blood withdrawn from the tails of anaesthetized mice; they were separated by centrifugation, washed three times with normal saline and lysed by the addition of approximately 5 volumes of distilled water. The cell stroma was removed by centrifugation and the supernatant fluid sterilized by filtration through a Seitz *EK* pad. The haemoglobin in the filtered solution was measured colorimetrically by the carboxyhaemoglobin (Haldane) method. Lysed guinea-pig cells were prepared in the same way as lysed mouse cells except that the blood was removed by cardiac puncture from animals anaesthetized with ether. Chromatographically homogeneous haemoglobin was isolated from human blood by the method of Allen *et al.*[4] and the solution sterilized by filtration through a cellulose ester membrane (Oxo, Ltd., London). Crystalline human haemoglobin was prepared from the same sample of blood by the method of Drabkin[5]. Two samples of crystalline horse haemoglobin were used (twice recrystallized grade *A*, Calbiochem; and Koch-Light Laboratories). The haemoglobin solutions were sterilized by filtration through a Seitz *EK* pad. The lysed red cells and the haemoglobin solutions were mixed with the bacteria immediately before intraperitoneal injection.

The methods of passive immunization, and infection with *P. septica* (strain *CN* 3449, Wellcome Research Laboratories), were the same as those described previously[1]. For all the experiments the dose of bacteria injected intraperitoneally varied between $1{\cdot}5 \times 10^5$ and $2{\cdot}9 \times 10^6$, but in any individual experiment the treated and control groups received identical numbers of organisms. The effects of lysed mouse red cells (equivalent to 7–28 mg haemoglobin) and the purified haemoglobins on passive immunity against *P. septica* are shown in Table 1. None of these compounds was toxic to normal mice.

E. coli strain 0111*B*4 was passaged in guinea-pigs by the same technique used for mice, but the lethal dose ($> 3 \times 10^7$ organisms) for guinea-pigs weighing 250–300 g remained relatively high. For the experiments with lysed red cells and haemoglobin shown in Table 2, $2{\cdot}5$ to $6{\cdot}6 \times 10^4$ *E. coli* were injected intraperitoneally. Neither the lysed cells nor the haemoglobin solution was toxic to normal guinea-pigs.

Table 1. EFFECT OF LYSED MOUSE RED CELLS AND PURIFIED HAEMOGLOBINS ON INFECTION BY *P. septica* (STRAIN *CN* 3449) IN PASSIVELY IMMUNIZED MICE

Haemoglobin intraperitoneally with *P. septica*	Amount of haemoglobin (mg)	Number of mice	Deaths (5 days)	Deaths (%)
Nil	Nil	327*	34	10
Lysed mouse red cells	7–28	60	58	97
Human haemoglobin: crystalline	7	10	10	100
Human haemoglobin: chromatographically pure	7	10	10	100
Horse haemoglobin: crystalline sample 1	28	10	10	100
Horse haemoglobin: crystalline sample 2	28	10	10	100

* Including controls from other experiments.

Table 2. EFFECT OF LYSED GUINEA-PIG RED CELLS AND CRYSTALLINE HAEMOGLOBIN ON INFECTION BY *E. coli* (STRAIN 0111*B*4) IN NORMAL GUINEA-PIGS

Haemoglobin intraperitoneally with *E. coli*	Amount of haemoglobin (mg)	Number of guinea-pigs	Deaths (3 days)	Deaths (%)
Nil	Nil	25	0	0
Lysed guinea-pig red cells	166–236	30	29	97
Lysed guinea-pig red cells	50	15	8	53
Human haemoglobin: crystalline	135	10	9	90

It is clear that homologous lysed red cells and a variety of purified haemoglobins can be effective in abolishing passive immunity to *P. septica* in mice, and enhance the virulence of *E. coli* in normal guinea-pigs. The mechanism of these reactions needs further investigation, but for the moment we have assumed, in the case of *P. septica* at least, that the reason for the effectiveness of these compounds is connected with the ability of the bacteria to acquire iron from the haemoglobin molecule. This is based on the observation that ferric ammonium citrate, a relatively simple iron compound, produces the same effect as haematin and haemoglobin. Whether the presence of free haemoglobin in wounds or infected tissue might play a part in encouraging bacterial infection is a matter for speculation, but it seems to be a possibility.

Mechanism of Closure of the Aortic Valve

THE human aortic valve consists of three cusps made of relatively inelastic, muscle-free material about 0·15 mm thick. It opens and shuts about once a second, and withstands a pressure difference of 100 mm of mercury when closed. It usually functions for 70 yr without failure, and works so efficiently that very little blood is regurgitated at each pulse. In order to support this large

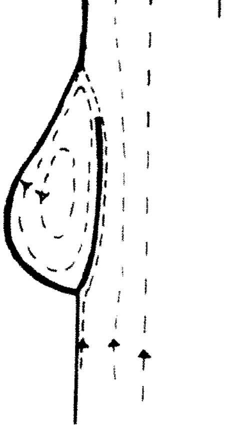

Fig. 1. Vortex formation in a sinus.

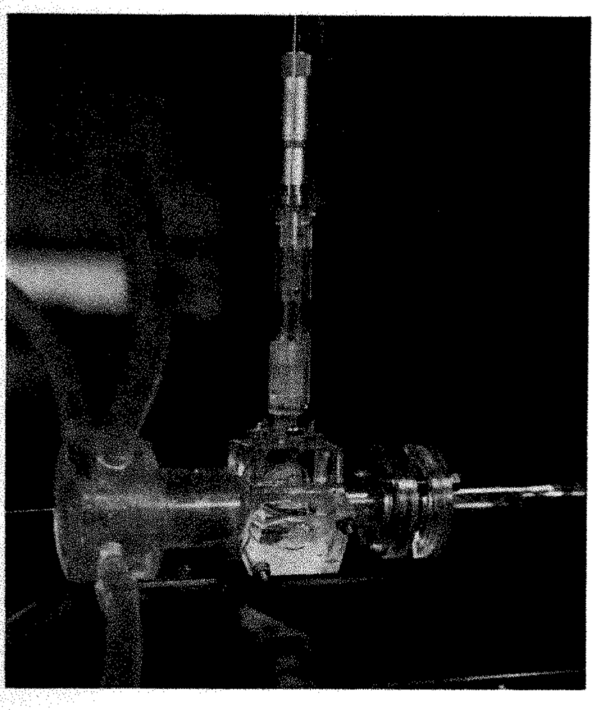

Fig. 2. Photograph of model valve in a tube of diameter 2·5 cm. A thin-film velocity probe is in the sinus, and is clamped in a traversing mechanism. The flow is from right to left.

pressure difference, the cusps must close simultaneously in all operating conditions and should not touch the wall of the aorta, for considerable reversed flow would then be required to close the valve. This action suggests a fluid dynamic control mechanism which positions the cusps away from the wall of the aorta, so that the slightest reversed flow will close the valve.

Such a mechanism is a vortex trapped between each cusp and its sinus (a bulge in the aortic wall). The vortices derive their energy from the forward going stream (Fig. 1), with the streamline along the cusp striking the distal end of the sinus in a stagnation point. This streamline divides, half reversing into the sinus and generating a vortex, the other half following the wall of the aorta distal to the valve. There is a phase difference between the main stream and the vortex; the vortex persists after peak systole, dominates the flow in the main stream and starts to close the valve. The vortices produce a thrust on both the cusp and the sinus wall, and the closure of the cusps is thus steady and synchronized. Leonardo da Vinci[1] correctly predicted the formation of vortices between the cusp and its sinus, and appreciated that these would help to close the valve, but thought the vortices were shed and featured in the dissipation of the kinetic energy of the fluid, for he was unaware of the circulation of blood.

To see if the trapped-vortex mechanism was an adequate explanation, a copy of a human aortic valve (Fig. 2), with rigid sinuses and aorta, was made in 'Perspex'. The cusps were made of nylon net impregnated with silicone rubber, and these were similar in thickness, smoothness, strength, shape and elasticity to physiological cusps. Two sets of identical cusps were made; one was fitted into a 'Perspex' tube with sinuses, the other into a tube with no sinuses. Both valves were tested statically for leakage, and were then tested dynamically in a pulsatile-flow rig, both together in series, and separately. The rig consisted of a constant head device for steady flow, together with a piston driven by a variable amplitude, variable frequency shaker which could produce sine waves of frequencies up to 10 c.p.s. The steady flow could be set at any value up to 9 l./min, and the shaker set to superimpose a suitable sine wave on the flow. With the flow at 3 l./min, and a pulse rate of 1 c.p.s., the valve with sinuses closed with about 4 per cent regurgitation (and some of this was caused by displacement of fluid by the cusps rather than leakage), but the valve without sinuses would not move, the cusps aligning themselves with the vessel wall. Not until the reversed flow had reached 23 per cent of the forward flow would this valve shut. Unlike the valve with open sinuses, this valve's cusps remained on the wall until it was violently shut by rapid reversed flow. The same results obtained at both greater and lesser flow rates.

In the valve with open sinuses, high energy vortices could be seen trapped between the sinuses and the cusps; peak velocity in the sinuses occurred after peak systole and the vortex persisted through the closure phase. These instantaneous velocities were measured with a heated thin-film gauge fitted into a needle of 1 mm diameter, and were shown to reach about two-thirds of the peak systolic velocity in the aorta. Apart from producing a thrust normal to the cusp (unlike the axial pressure gradient) and initiating valve closure, the vortices would also scour out the sinuses and prevent the formation of thrombi behind the cusps in blood flow.

Dr Grant de J. Lee of the Radcliffe Infirmary, Oxford, has used this velocity probe in animals, and the traces show that the flow is laminar (except possibly very briefly at peak systole). The flow in the model valve was laminar at 5 l./min, and thus might form the basis for a design for an artificial valve which does not cause haemolysis.

IMMUNOLOGY

Cellular Immune Competence of Spleen Bursa and Thymus Cells

IN the chicken there are two central lymphoid organs, the thymus and the bursa of Fabricius. Recognition of the roles of these two organs in the ontogeny of immunological responsiveness permits definition of two functionally and morphologically distinct lymphoid cell lines[1-4]. The avian thymus, like the mammalian thymus, is essential to the normal development of a population of small lymphocytes and cellular immunity, while the bursa of Fabricius plays a similar part in the ontogeny of the plasma cell line and humoral immunity[4]. In addition, the thymus may contribute towards full development of humoral immune responsiveness[4-6]. A bursa equivalent has not been identified in all species, but evidence indicates that lymphoid tissues associated with organized gut exercise these functions in rabbits. These lymphoid tissues include Peyer's patches, sacculus rotundus and appendix[3,7].

While the functions of the thymus and bursa are different, the organs show similarities of development and lympho-epithelial morphology which seem to characterize central lymphoid tissues. Both are composed of follicles of lymphoid tissue with cortical and medullary organization[1], develop independently of antigenic stimulation[8], and possess relatively few antibody synthesizing cells[9]. Bursal lymphocytes differ from thymus lymphocytes in that the former are larger and contain a high RNA/DNA ratio and an abundance of polyribosomes[2,10]. In an effort to detect possible differences in the intrinsic immunological competence of bursal and thymus lymphocytes, we have measured the graft versus host activities of these cells. The data obtained are in accord with the hypothesis of compartmental differentiation of two separate lymphoid cell lines and afford further characterization of the avian thymus and bursa of Fabricius.

In this investigation, the immunological competence of bursa, spleen and thymus cells was estimated by a method similar to that used by Simonsen[11]. With this assay system the degree of splenomegaly produced by a given number of lymphoid cells is an index of their cellular immune potential[4]. Donor organs were removed from exsanguinated, 10 week old Arbor White Rock donors and placed in chilled beakers. Bursae were cut in half and swirled in saline to remove the slime which usually coats their epithelial surface. To reduce bacterial contamination, each organ was rinsed in saline containing penicillin (300 U/ml.) and streptomycin (300 μg/ml.). The tissues were transferred to Petri dishes containing a 40 mesh stainless steel screen and 10 ml. of chilled Eagle's basal medium, penicillin (100 U/ml.) and streptomycin (100 μg/ml.). Crude cell suspensions were prepared by rubbing the organs against the screens. These preparations were transferred to test tubes, and the non-cellular debris and clumped cells were allowed to settle for 15 min. Cells remaining in the supernatant were washed three times by centrifugation and resuspended in fresh medium. The number of viable cells was determined by counting in a haemocytometer those cells which were unstained after 10 min of exposure to 'Erythrosin-*B*' (0·2 mg/ml.) in balanced salt solution. As a control, some cells were killed by heating at 56° C for 1 h. Convenient numbers of viable or heat killed cells were injected into an allantoic vein of 14 day old Ghostley White Leghorn embryos. Five days later, the gross pathology as well as spleen weights and body weights of injected embryos were observed and recorded.

The spleens shown in the upper portion of Fig. 1 are representative of those seen in embryos which received 10^6 viable spleen, bursa or thymus cells. Those in the lower portion came from embryos injected with heat killed cells. The white lesions and splenomegaly are the results of graft versus host reactions and can be taken as evidence of the cellular immune competence of the donor cells. Spleen and thymus cells appear competent, while bursal cells fail to elicit the reactions. The degree of splenomegaly induced by injections of $4·0 \times 10^5$ viable bursa, spleen or thymus cells, shown in Table 1, indicated that spleen and thymus, but not bursa, produced significant splenomegaly. Splenic cells have a greater capacity than thymus cells to elicit graft versus host reactions; heat killed cells did not elicit significant splenomegaly.

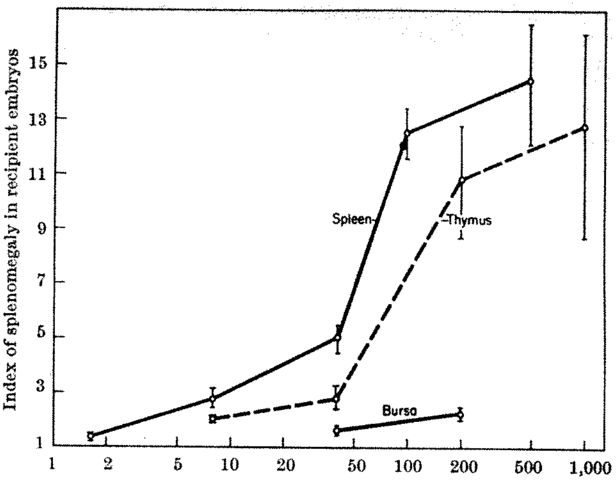

Fig. 2. Relative graft versus host activity of lymphoid cells of the thymus, spleen and bursa of Fabricius. Vertical bars indicate standard errors.

To determine whether the differences were attributable to differences in the ratio of competent to non-competent cells in the spleen and thymus or to an intrinsic difference in immunological activity per cell, we injected different numbers of cells from each organ. It was reasoned that if the cells from the three organs were intrinsically different in degrees of competence the slopes of the dose-response curves would be different. If, on the other hand, the differences previously mentioned were caused only by the ratio of competent to non-competent cells in a given organ, the slopes of the dose-response curves should be parallel. The indexes of splenomegaly are plotted against the logarithm of the number of donor cells as previously carried out by Sosin *et al.* for mice[12]. Our results, summarized in Fig. 2, show that the spleen has five times more capacity to elicit graft versus host reactions than does the thymus, but the slopes of the dose-response curves are similar. This finding indicates that the specific activity of avian spleen and thymus lymphocytes is the same. Variability inherent in the assay, however, might not permit the detection of small differences. Perhaps even more significant is the relative inactivity of bursal cells. Bursal cells elicited some splenomegaly, but because this was detected only with very large numbers of donor cells, the response could be attributed to unavoidable contamination with blood cells.

The absence or relative infrequence of graft versus host inducing cells in the bursa of Fabricius as compared with the thymus parallels previous findings showing that the thymus but not the bursa functions in the ontogeny of cellular immunity[4,13,14]. A question which remains unanswered concerns the role of the thymus in the ontogeny of humoral immunity. Thymectomy of very young animals (avian and mammalian) has been shown to decrease humoral immune responsiveness to some antigens in later life[4–6,15–18]. One explanation for this effect is that some of the lymphoid cells of the bursa are derived

Table 1. GRAFT VERSUS HOST ACTIVITY OF SPLEEN, THYMUS AND BURSA LYMPHOID CELLS

* Cells prepared from the spleen, thymus or bursa of 10–13 week old White Rock donors were injected into 14 day old White Leghorn embryos. Recipients were killed 5 days later, and spleen and body weights and gross spleen appearance were recorded.

from the thymus. This hypothesis now seems less likely because lymphoid cells derived from thymus would be expected to be capable of the graft versus host reaction. It is not clear whether this effect of thymectomy is a direct result of the absence of the thymic function or an indirect result of depression of bursal differentiation as a consequence of lack of vigorous thymus-dependent defence mechanisms[19,20]. Alternatively, thymus could influence bursal cells or the bursa-dependent population by humoral means without providing cells directly to the bursa, or a population of lymphoid cells may migrate directionally from the bursa to the thymus as previously suggested for embryonic and young adult chickens[21].

These findings may also be relevant to future attempts at restoring the immunoglobulin-producing system of cells in immunoglobulin deficient patients. It has been shown earlier that bursal cells can restore this cell system in agammaglobulinaemic chickens. Cells of the bursa-equivalent should have similar functional capabilities and should not produce untoward graft versus host disease in recipients. Thus host compatibility would be the only limiting requirement in such restoration.

Japanese Haemoglobin Variant

RECENT haemoglobin surveys in the south-western area of Japan have revealed a great variety of abnormal haemoglobins in Japanese individuals despite the rarity of haemoglobinopathy. In Japan, at least thirteen abnormal haemoglobins have been identified by elucidation of amino-acid substitution, and similar studies are now in progress on ten other variants.

As part of an extensive screening programme for abnormal haemoglobins in Japanese individuals, some two thousand patients who visited the Yamaguchi Prefectural Central Hospital in Hofu City, Yamaguchi Prefecture, have been tested by agar gel electrophoresis (pH 7·0 and 8·6)[1] since 1964. An abnormal haemoglobin was discovered in only one of them—a 55 year old woman who came to the hospital because of abdominal discomfort and who was diagnosed, by means of X-ray study and gastrocamera, to be suffering from gastritis. The red blood cell count was 400×10^4, haematocrit was 31·3 per cent, reticulocyte count was 1·3 per cent and white blood cells amounted to 6,500 with normal differential count. Her only child did not carry the abnormal haemoglobin and her parents were dead. When the haemolysate was subjected to agar gel electrophoresis at pH 8·6, the abnormal haemoglobin separated as a distinct band which was situated more towards the anode than the normal Hb A band, but it was inseparable from Hb A at pH 7·0. Its electrophoretic mobility in starch gel electrophoresis (pH 8·6)[2] suggested that it had two extra negative charges per molecule (Fig. 1). Hb F content of the haemolysate was 0·91 per cent by Singer's method[3]. Solubility of the haemolysate in the deoxygenated form[4] was normal. This fast-moving abnormal haemoglobin was named Hb Hofu, after the name of the town where the propositus lived. Hb Hofu content of the haemolysate was 50·6 per cent; this was determined by scanning ($\lambda = 570$ mμ) the agar gel after electrophoresis.

Pure Hb Hofu was prepared by starch block electrophoresis[5] at pH 8·6. Its β chain anomaly was demonstrated by a hybridization test with canine haemoglobin[6], in which the migration during starch gel electrophoresis at pH 8·6 of the hybrid molecule, $\alpha_2^{\mathrm{Can}}\ \beta_2^{\mathrm{Hofu}}$, was faster than the corresponding hybrid, $\alpha_2^{\mathrm{Can}}\ \beta_2^{\mathrm{A}}$, while the migration of $\alpha_2^{\mathrm{Hofu}}\ \beta_2^{\mathrm{Can}}$ was equal to that of $\alpha_2^{\mathrm{A}}\ \beta_2^{\mathrm{Can}}$. Paper electrophoresis (pH 8·6) of globin in 7 molar urea[7] also revealed the fast-moving β chain anomaly.

Globin was prepared from the purified Hb Hofu by Anson–Mirsky's technique[8] and the β chain was separated from the α chain by sodium ion gradient chromatography in 8 molar urea on carboxymethyl cellulose column[9]. The β chain was aminoethylated with ethyleneimine[10] before it was digested with trypsin. Fingerprints were made according to Ingram's[11] and Baglioni's[12] techniques. An abnormal spot which was located more towards the anode than the β Tp-1 spot, and which occupied the position of

α Tp-4, was clearly visible (Fig. 2). The β Tp-13 spot was present but was much weaker than the other spots in ninhydrin coloration. The abnormal spot was cut out from the fingerprints; the peptide was eluted into 6 normal hydrochloric acid and digested at 110° C for 20 h in a vacuum-sealed tube. The amino-acids of the acid hydrolysate were quantitatively analysed[13] by the Yanagimoto amino-acid analyser (Table 1). The amino-acid constituent of the abnormal peptide completely coincided with β Tp-13

121 122 123 124 125 126 127 128 129 130 131 132
Glu–Phe–Thr–Pro–Pro–Val–Gln–Ala–Ala–Tyr–Gln–Lys

except for the absence of Val and the presence of an extra Glu (ref. 14). It was therefore presumed that the abnormal peptide spot was derived from β Tp-13 and that Glu or Gln had substituted for Val β 126. Because an amino-acid substitution of Gln for Val would not cause any change in either the electric charge of the molecule or the sub-unit, nor in the migration towards the anode of the β Tp-13 spot, Glu (not Gln) seemed to be the most probable substitute for Val. The faint spot coincident with the normal β Tp-13 spot was regarded as a derivative from a contaminating normal β chain. We conclude therefore that Hb Hofu is a new abnormal haemoglobin which can be expressed by the formula $\alpha_2^A \beta_2^{126\ \mathrm{Glu}}$.

Amino-acid substitution of Glu for Val, the reverse of Hb S, has been known in Hb $\mathrm{M_{Milwaukee\text{-}1}}$ (ref. 15) and Hb New York[16], but Hb Hofu will be the first case in which a substitution of the 126th amino-acid of the β chain was discovered. Hb Hofu seems to be a very rare abnormal haemoglobin which is not associated with the clinical symptoms.

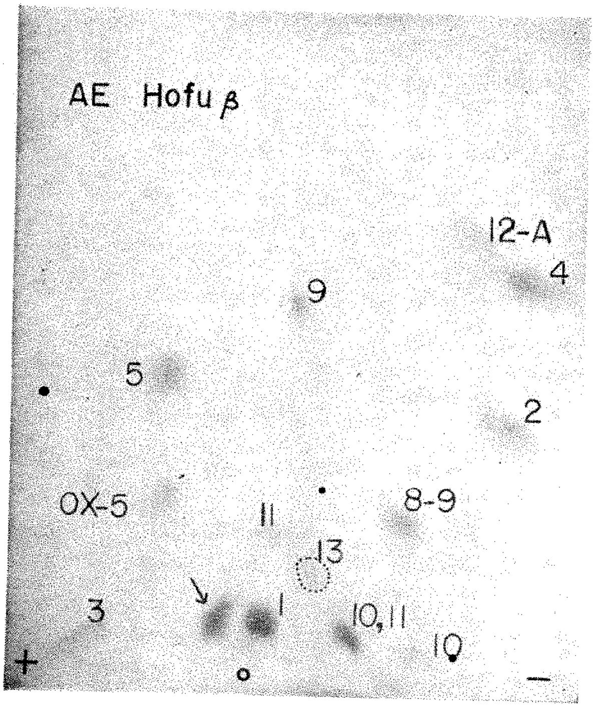

Fig. 2. Fingerprint of the aminoethylated β chain of Hb Hofu (by Baglioni's method). Numerals refer to β Tp numbers. The abnormal spot is indicated by an arrow. It is considerably biased from the position of the corresponding normal β Tp-13 spot (encircled by dotted line) toward the anode and the bottom.

BIOLOGY

Mycological Aspects of Diseased Atlantic Salmon

As part of the research programme on fish disease mentioned before[1], we have undertaken an investigation to establish the role of fungi in the disease termed ulcerative dermal necrosis (UDN) which affects freshwater fish, particularly salmon. The fact that fungi are associated in some way with this disease is indisputable; indeed, diseased fish in the rivers are recognized chiefly by the presence of white fungoid patches.

We found that the disease pattern is as follows: initially the disease becomes apparent as grey-white bruise-like areas on the surface of the fish. These areas then develop fungal growth which is obvious to the naked eye, with subsequent haemorrhagic ulcers usually developing at each site. The musculature is often exposed by these ulcerous lesions. Similar autopsy findings in eels are reported by Hoshina and Ookubo[2]. The fungus appears as an off-white raised excrescence usually covering the lesions. In colour the diseased areas vary from off-white to dark brown depending on how much blood or silt has been deposited in the fungal mycelium.

While there is a dearth of literature on fish mycopathology, nevertheless certain work[2–5] has established the pathogenicity of fungi towards freshwater fish. It is a popular belief that one fungus only is found on fish—"fish-mould" has become synonymous with the fungus *Saprolegnia*. Investigation shows that many fungi are involved in disease of fish, mostly representatives of the family *Saprolegniaceae*. Apart from various species of the genus *Saprolegnia*, members of the genera *Achlya*, *Dictyuchus* and *Aphanomyces* are listed in the literature mentioned here as lethal parasites of fish. The parasitic potential of the family is exemplified by the crayfish plague fungus, *Aphanomyces astaci*, which Unestam[6] reports as causing 100 per cent mortality in attacked populations of *Astacus astacus*. Unestam believes that this species of crayfish faces extinction in Europe because of the severity of the attack. Fungal activity obviously plays a prominent part in ulcerative dermal necrosis whether as (*a*) a lethal primary parasite, (*b*) a secondary invader of already debilitated tissue and the eventual killer, or (*c*) merely as a saprophyte or scavenger of dead tissue. In view of the fact that there is no general agreement as to the cause of the disease, to dismiss the fungal infection as secondary (ref. 7 and numerous press reports) is to us an unacceptable premise.

As part of the present investigation the general mycoflora of healthy and diseased fish was surveyed. Since 1966, some ninety salmon (*Salmo salar*), smolts and adults and a more limited number of brown trout (*Salmo trutta*), fry and adults, have been examined in detail. Diseased salmon were obtained from the rivers Shannon, Liffey, Lee, Blackwater (Cork) and Dargle; diseased trout from the Lagan and Dargle. Healthy salmon were obtained from the rivers Boyne and Owenea. Where possible fish were taken directly from the water to polythene sleeving and transported immediately to the laboratory. Due caution was exercised where contamination from, for example, soil was suspected.

The fungi most commonly isolated from the surface of healthy and diseased fish, apart from lesions, include species of *Penicillium*, *Fusarium*, *Mucor* and *Trichoderma*, together with numerous pycnidial fungi, yeasts and unidentified imperfect types. Several hundred isolates now await specific identification. None of these fungi was visible macroscopically. It has not been established whether they are present as actively growing mycelia or merely as spores adhering to the surface mucus. Most of these fungi are non-aquatic and are presumably present in rivers as aliens from soil and air[8]. The mycoflora is not constant from one fish to another and it has been difficult to establish whether a fish surface supports a recognizable fungal community. From results obtained so far, it seems that there is no constant mycoflora associated with fish surfaces but rather that its composition varies considerably from one individual to another and from river to river, largely depending on environment, for example the extent of river pollution or flooding. Considering the specialized demands of many aquatic phycomycetes it is not surprising that so few have been isolated in this survey.

Saprolegnia alone has been isolated constantly from the lesions of diseased fish. Not only has it been isolated externally but also internally from the musculature, to a depth of 1·5 cm, and occasionally elsewhere other than from visibly diseased areas. This fungus has been isolated at all observable stages of the disease, even from the "white patches"[7] of the presumed pre-mycotic stage. With few exceptions the *Saprolegnia* isolates share one feature in common, that is the absence of sexual reproduction. This character together with the type of sporangial branching (cymose) and parasitic nature on fish would until recent times be sufficient evidence for their common identification as *Saprolegnia parasitica* Coker (Coker)[9,10]. Certain strains of this fungus, however, given suitable conditions and sufficient time—in some instances up to a year—have been reported as forming sexual organs[5]. For the positive identification of this species it is now considered necessary to observe the characteristics of these structures[11]. Experiments, using sterols, aimed at inducing the initiation of a sexual stage in our isolates have not been successful.

The reluctance of these isolates to reproduce sexually has led to the suggestion that heterothallism may be operative in the genus. A programme of pairing the isolates has been undertaken to investigate this possibility. So far most of the paired cultures have not shown any complementary response. In one case, however, sexual structures were formed at the interface of two asexual isolates. This has given impetus to more intensive research on the possible existence of heterothallism in the genus *Saprolegnia*. Although the tardiness of our isolates to produce oogonia suggests that they are *Saprolegnia parasitica*, a definite identification is still outstanding pending further evidence of the formation of a sexual stage. Our tentative identification of these isolates as *Saprolegnia parasitica* is particularly significant. Of all the saprolegniacious fungi known to attack fish, *Saprolegnia parasitica* is the one most frequently reported as a fish parasite. Tiffney[3], Hoshina and Ookubo[2] and Vishniac and Nigrelli[4] have shown experimentally that this species can act as a lethal primary parasite of healthy fish.

The spread of the disease is most marked during periods of low water temperature and, conversely, with increasing water temperatures there seems to be a diminution of the disease. A relationship between low water temperature and parasitic potential of *Saprolegnia* has been considered for some time as a possible important factor governing epidemics of fungus disease in fish. Thus, Hoshina and Ookubo[2] observed the cessation of fungus epidemics in eels as water temperatures approached 18° C. We have obtained similar evidence from a recent outbreak of mycoses at the Mullingar fish rearing station where several hundred brown trout fry died within days. Two fungi, *Saprolegnia ferax* and a species of *Pythium*, were isolated from these fish. It seems to be significant in connexion with this outbreak that the water temperature dropped from 16° to 10° C (Ryan, personal communication) in the week before the onset of the disease. Accordingly, the apparent correlation between the spread of fungus in ulcerative dermal necrosis and water temperatures merits investigation.

It has frequently been suggested that freshwater fungi cannot live in salt water, but we found that *Saprolegnia parasitica* (culture obtained from Centraalbureau voor Schimmelcultures, Baarn, Holland) has a high salinity tolerance. The growth of *S. parasitica* in a range of concentrations of sodium chloride and seawater was examined by the method of Scott and Warren[12]. Using colony area as a criterion, growth in a solution of 3·5 per cent sodium chloride was half, and in 100 per cent sterile seawater two thirds, that obtained in controls. It is emphasized that in these particular experiments optimal growth conditions were provided for the fungus, which experienced no competition from the usual biota of seawater. Reference is made to Te Strake[13], who found that members of the Saprolegniaceae could grow and sporulate in brackish waters if temperature and nutritional levels were suitable. She also emphasized the futility of habitat nomenclature, such as "fresh water" fungi, when "fresh water" fungi given appropriate conditions can become "brackish water" forms. Vishniac and Nigrelli[4] have suggested that the Saprolegniaceae may parasitize fish of brackish water. Salmon recently returned from the sea, as evidenced by the presence of sea-lice on the fish, have been taken from estuarine waters and have shown symptoms of ulcerative dermal necrosis; *Saprolegnia* has been isolated from these fish. It is therefore possible that the fungus could colonize salmon immediately they entered the river estuary.

Inoculation experiments now in progress in this laboratory are expected to furnish definitive information about the role of *Saprolegnia* in ulcerative dermal necrosis. On the basis of existing evidence, it seems improbable that it functions merely as a scavenger. It is more reasonable to suggest that the fungus is the primary parasite in ulcerative dermal necrosis or alternatively that an extremely close relationship exists between an unknown primary parasite and *Saprolegnia*.

We thank Miss Angela O'Gorman for her assistance. This work was supported in part by the award of a fellowship to one of us (H. F.) by the Department of Agriculture and Fisheries, Dublin.

Prey Selection: Oddity or Conspicuousness ?

PIELOWSKI has shown that goshawks (*Accipiter gentilis*) select as prey pigeons (*Columba livia*) which differ in colour from most pigeons which are present in Polish forests[1,2]. Salt[3] has shown how these and other experimental results fit rather well into the generalization that predators preferentially capture prey animals which are odd, or which differ in some way from most prey. As Pielowski noted, however, it is probably easier for a goshawk to fix its attention on the odd-appearing member of a flock, and it is possible that the goshawks were merely taking conspicuous individuals out of the flock. Selection for conspicuous prey has been amply verified by experimentation[4-8]. I have attempted to determine the parts played by oddity and conspicuousness in prey selection.

A tamed hawk (*Falco sparverius*) preyed on laboratory mice which were either white or which had been dyed grey. In each experiment, nine mice of one colour and one of the other were presented on a table which was coloured to match one or the other colours of mice. Each of the two colour combinations of mice was replicated fifty times on each of the two colours of background, giving a total of two hundred experiments.

Experimental series *A* and *B*, in which the background was grey, clearly show that the hawk selected conspicuous, but not odd, prey (Table 1). In view of these results, I suggest a reconsideration of the generalization that odd prey is preferentially selected by predators. In series *C* and *D*, where grey mice were conspicuous, prey selection did not differ from random. I suggest that this is a result of a conflict in preference for (*a*) white and (*b*) conspicuousness. The hawk took a significantly longer time (*t* test, 95 per cent level) to select a mouse in series *C* and *D* than it did in series *A* and *B* (Table 1), which can be considered as evidence for conflict. I cannot explain this unexpected preference for white mice other than by suggesting that the hawk may have become accustomed to preying on white mice in series *A* and *B*. The hawk may thus have formed a "specific searching image"[9] in series *A* and *B* and maintained it throughout series *C* and *D*. Further experiments are in progress.

Table 1. PREY SELECTION EXPERIMENTS

Series	No. of experiments	Mice presented in each experiment		Background	Mice captured		P*	Mean reaction time (sec)	Standard error
		Grey	White		Grey	White			
A	50	9	1	Grey	37	13	0·0002	261	44·2
B	50	1	9	Grey	0	50	0·03	230	44·1
C	50	9	1	White	44	6	0·30	374	41·0
D	50	1	9	White	6	44	0·30	394	47·3

Pigmentation in the Radial Nerve of *Diadema antillarum*

RECENT examination by phase-contrast microscopy of teased, fresh or macerated radial nerve, or of frozen sections in *Diadema antillarum*, has shown the presence of reddish cells that are neither amoebocytes nor chromatophores, but which resemble neurones in their general form (Figs. 1 and 2).

The presence of a reddish pigment in the radial nerves of this echinoid is of special interest because in experimental conditions the nerve can serve as a photoreceptor in the characteristic shadow response[1-2]. Photosensitivity is maximal between 455 and 460 mμ (ref. 3), and the pigment, when extracted in acidified diethyl ether, absorbs maximally in the visible range at 465 mμ. Absorption of both visible and ultraviolet radiation corresponds closely with that of the reddish pigment which can be extracted from the skin[4] and which is now known to be echinochrome *A*. The near coincidence of these maxima coupled with the presence of the pigment in the photosensitive skin as well as in the radial nerve has caused speculation that the pigment may be involved in photoreception[5,6]. Our recent discovery in the radial nerve of similarly pigmented cells which resemble neurones therefore reinforces the idea.

Caution has already been urged, however[7]. Most of the red pigment in the radial nerve is in the ubiquitous amoebocytes or in their disorganized remains, and the pigmented presumptive neurones are rare. On the other hand, photoreceptors for the shadow response seem to be widespread in the nerve and it is unlikely that amoebocytes are directly involved. Again, previous determinations of spectral absorption have relied entirely on extracted

Figs. 1 and 2. Two of the pigmented structures which have been interpreted as neurones in the living radial nerve of *Diadema*, which were examined by microspectrophotometer. Scales: Fig. 1, 5·3 mμ; Fig. 2, 4·6 mμ.

pigment. Determination of the absorption spectrum of the presumed neuronal pigment *in situ* is therefore crucial and this has now been achieved by microspectrophotometry. Absorption is maximal between 540 and 560 mμ, so that whatever the precise nature and function of the presumptive neurones could be, they are unlikely to be involved as receptors in the shadow response.

Vision Index for Isopod Crustacea related to Latitude and Depth

THERE has been no systematic study of the distribution of eye-bearing and blind benthic crustaceans in relation to the depth of the sea at which they occur. It has, however, been known for many years[1] that many deep-sea isopods are blind and it has also been known that most intertidal species have well developed eyes[2]. We have examined the bathymetric range of many species of isopods in order to determine the correlation between presence or absence of eyes, latitude, depth and light penetration. To do this we have developed a visual or ocular index.

The ocular index (*O.I.*) can be defined as the percentage of species of isopods in the total isopod fauna which have eyes. In order to provide an expression which can be related to any latitude, the 50 per cent level of species which have eyes can be defined as an ocular index of 50 ($O.I._{50}$).

The data on which this study is based come from collections off Beaufort, North Carolina (35° N.) (collections made by R/V Eastward, NSF grant), off Lima, Peru (10° S.) (collections made by the R/V Anton Bruun, Cruise 11), and in the Antarctic (60° S.) (collections made by USNS Eltanin). Added data were compiled from the sub-Antarctic[3,4] and the Arctic[1,5,6] and for the tropics[7-11]. The number of benthic species of isopods which were utilized in the determination of ocular index is given in Table 1 with reference to five different latitudes and seven different levels of depth. The total number of organisms involved in this study exceeds fifteen thousand, but Table 1 records only the number of species.

Table 1. NUMBER OF SPECIES OF ISOPODS AND PERCENTAGE WITH EYES IN RELATION TO DEPTH AND LATITUDE

	65° N.		35° N.		10° N.		15° S.		70° S.	
	No. spp.	%	No. spp.	%	No. spp.	%	No. spp.	%	No. spp.	%
Intertidal 0–2 m	12	100	32	97	42	100	37	100	—	—
Subtidal 20 m	17	65	26	93	5	100	12	100	7	71
Shelf 40–200 m	50	46	25	92	9	100	31	97	31	58
Slope (*u) 200–1,000 m	69	17	13	69	—	73*	7	71	25	36
Slope (m) 1,000–2,000 m	43	8	9	0	5	20	8	25	32	13
Slope (L) 2,000–4,000 m	45	2	23	1	16	0	49	0	30	3
Abyss 4,000–6,000 m	3	0	8	0	9	0	9	0	22	0

* Asterisk denotes the point determined from the curve.

Except perhaps for absence of pigment, the absence of eyes in a species of marine isopods does not correlate with other changes in external morphology. Absence of eyes seems to be a frequent change among the species of many genera. Good examples of this can be found in the typically shallow water genera *Serolis*, *Janira*, *Munna*, *Cirolana*, and so on, which have eye-bearing as well as eyeless species. In contrast, all known species of typically abyssal genera (*Haploniscus*, *Mesosignum*, *Macrostylis*) lack eyes.

The proportion of eyeless to eye-bearing isopods usually shows an increase with depth. A comparison of the data from various latitudes shows two general patterns. The first is a high latitude or polar curve in which the percentage of eye-bearing species shows an immediate drop from the shelf to the great depths (Fig. 1). In this case, the $O.I._{50}$ is located at shallow depths between 100 and 500 m. The second pattern (Fig. 1) is exhibited between latitudes 35° N. and 15° S. where there is no abrupt decrease in eye-bearing species in the shallow waters (100–500 m). Instead there is a more or less gradual decline in eye-bearing species with depth until no eye-bearing species are present. The data suggest the $O.I._{50}$ is found at progressively greater depths as latitude decreases. For example, the $O.I._{50}$ at 35° N. is at 1,280 m. This striking picture of equatorial submergence of the $O.I._{50}$ is shown in Fig. 2, where the $O.I._{50}$ data are plotted against latitude.

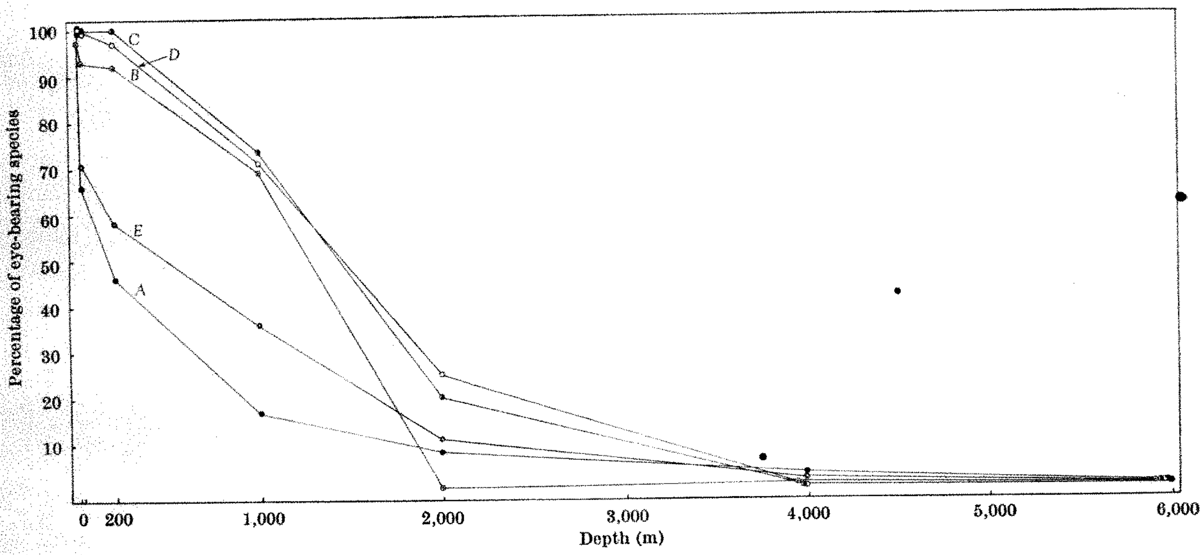

Fig. 1. Percentage of eye-bearing isopod species in relation to latitude and depth: ●, *A*, 65° N.; ○, *B*, 35° N.; ◑, *C*, 10° N.; ○, *D*, 15° S.; and **O**, *E*, 70° S.

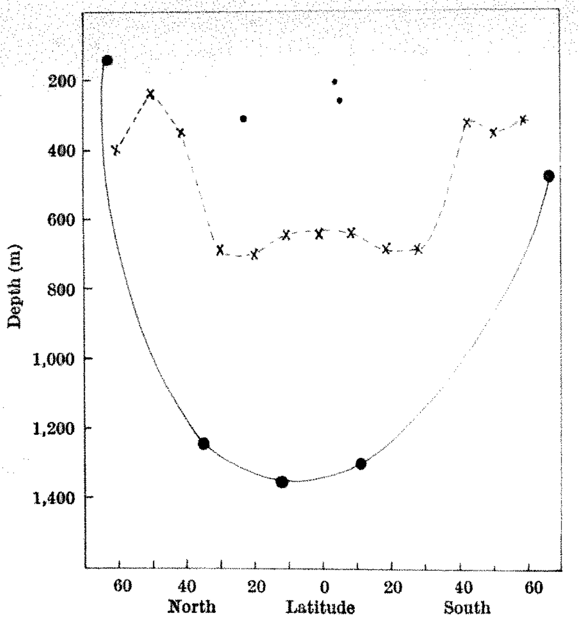

Fig. 2. $O.I._{50}$ for marine isopod species in relation to depth and latitude, as derived from the distribution of vertical light extinction coefficient of surface water (after Neuman and Pierson[12]). Curve with dotted line represents light penetration north to south along 40° W. in the Atlantic.

Several factors could be associated with the phenomenon of the equatorial submergence of the $O.I._{50}$. One might believe that variations in depth of penetration of visible light with latitude would show a direct relationship to the $O.I._{50}$. Indeed, the shape of the two curves is similar with visible light penetrating to lesser depths in polar regions and to greater depths in low latitudes. (At high latitudes the penetration of light is obviously minimal during winter months and maximal during summer.) The vertical extinction coefficient of light in surface water at 50° N. and 50° S. is greater than four, but is less than two in the Sargasso Sea[12]. Penetrating daylight is visible to the human eye down to depths of about 700 m in the Sargasso Sea, but the $O.I._{50}$ is located at 1,300 m or about twice the maximum depth of penetration of light. Light may be important and indeed probably is, but its relation to the $O.I._{50}$ is not clear. It is clear that a sizable proportion of the species have eyes well below the penetration of visible light. The answer could lie in the evolutionary mechanisms which are related to the ecology and dispersion of the various species in relation to visible light. It could be assumed that species which live in the light and which have eyes have an advantage, while those without eyes are at a disadvantage and should be eliminated through natural selection. Selective mechanisms could account for the fact that the $O.I._{50}$ is well below the penetration of visible light. What eye-bearing species living in deep water see, and how shallow species without eyes survive, could be contingent on many ecological and evolutionary factors such as mutation rates, the intensity of competition, and the dispersion capacities of the various species, and so on. The possible role of environment bioluminescence might be looked into.

Another parameter which might influence the tropical or equatorial submergence of the $O.I._{50}$ is temperature. Ekman[13] has described and discussed the equatorial submergence of marine animals. Species living in shallow water at high latitudes often inhabit deeper water nearer the equator. Ekman states "submergence is simply a consequence of the animals' reactions to temperature. Cold water animals must seek colder, deeper water layers in regions with warm surface water . . .". But this explanation, Ekman admits, presupposes a certain degree of stenothermy in the organisms in question. Ekman's explanation of submergence may be valid. Precisely what direct effect the latitudinal variations in temperature can have on the presence or absence of eyes is not clear because the curve for the $O.I._{50}$ does not follow a given isotherm from the poles to the tropics. Ekman[13] was dealing with a submergence by populations of the same species in his discussion of tropical submergence. In our data which are at present being prepared on the benthic isopods of the Peru–Chile Trench, more than fifty different species are involved in 80–90 per cent of the tabulations and therefore the submergence by individual species that Ekman describes as tropical submergence cannot explain the submergence of the $O.I._{50}$. This latter figure applies to the isopod population as a whole at a given depth and latitude.

The abrupt drop in percentage of species which bear eyes in polar regions could result simply from the high proportion of typically abyssal genera which occur in the shallow water (100–500 m) of polar latitudes (Fig. 3). The data show that blind abyssal genera are found in shallow water in the polar regions, but only in deeper water at lower latitudes. This phenomenon we call polar emergence of abyssal genera.

There have been many attempts to define the upper and lower bathymetric limits of the abyssal zone[14] in the oceans. Most definitions are based on arbitrary depths of convenience for tabulation rather than on biological criteria. It should be noted (Table 1) that the $O.I._0$ (all species blind) occurs between 4,000 and 6,000 m at all latitudes. The upper depth limit of 4,000 m coincides closely with Vinogradova's[15] average upper limit of the abyssal zone at 3,600 m. Between 2,000 and 4,000 m, 2–3 per cent of the isopod species have eyes at the poles, whereas at intermediate latitudes the eye-bearing percentage is 0·1 (Table 1). Thus the eye-bearing species

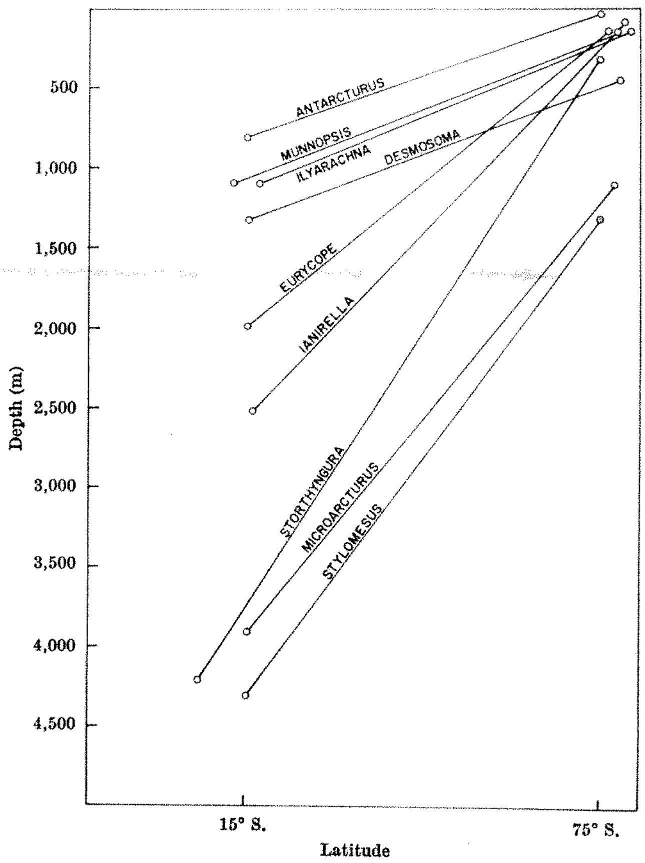

Fig. 3. Minimum level of bathymetric distribution of isopod genera at lat. 15° S. and 70° S., with a demonstration of polar emergence of abyssal genera.

obviously show a greater depth penetration at the poles than at intermediate latitudes. This phenomenon occurs in parallel with the polar emergence of typical abyssal genera. These phenomena coincide with water temperatures which are not more than 3° C above zero and show no relationship to light penetration.

An equatorial submergence of species which bear eyes has been well documented in large collections of marine Isopoda. Conclusive correlations between this phenomenon and visible light penetration into the sea are not, however, apparent because many eye-bearing species occur far below the limits of visible light. The direct effects of temperature are even less clear.

Co-ordinated Neuromuscular Activity in Insect Spiracles at Sub-zero Temperatures

DIAPAUSING pupae of some saturniid moths overwinter in an environment in which temperatures may drop to −30° C. In such conditions of cold and low humidity there are opportunities for pupae to desiccate; however, this does not happen. The primary sites of pupal water loss are seven pairs of functional spiracles. We have examined the functional behaviour of these spiracles at sub-zero temperatures. Apart from the interest this might have for students of insect physiology, it seemed of general interest to observe the effects of sub-zero temperatures on co-ordinated neuromuscular activity, and on the sensitivity of the spiracular control system to carbon dioxide and oxygen. The experiments also examine the question of pupal water loss at low temperatures.

The opening of each spiracle is regulated by a spiracular valve, moved by a single closer muscle which is opposed by an "elastic" ligament. The muscle is innervated by a nerve from the central nervous system[1]. Gas exchange across the spiracles has been shown to be discontinuous from +25° to 0° C. (A. P. Brockway and H. A. Schneiderman, in preparation).

Discontinuous respiration is characterized by a series of cyclical events which are causally connected[2]. Metabolic carbon dioxide is stored in the pupa, and released periodically in bursts. A burst is initiated when intratracheal pCO_2 reaches a triggering threshold. During a burst the spiracular valves open widely, and the intratracheal barometric pressure remains at atmospheric. Following a burst the spiracular valves constrict, and intratracheal barometric pressure falls as the tracheal oxygen is removed by the tissues. Intratracheal pCO_2 begins to rise and pO_2 falls steadily. When the pO_2 falls to a certain level the valves begin to open and close continually or "flutter". Intratracheal pressure rises and falls in "microcycles" throughout the flutter period. The flutter period is terminated when the intratracheal pCO_2 again reaches the triggering threshold and the valves open widely.

Prolonged valve opening is a response of the spiracular closer muscle to high carbon dioxide concentrations or to anoxia; this response persists after the closer muscle has been denervated[3]. Fluttering of the valves, on the other hand, ceases after muscle denervation[3,4], and is controlled by the pO_2 in the tracheae supplying the segmental ganglia[4]. Thus flutter indicates the continuing response of the central nervous system to oxygen.

Discontinuous respiration has been suggested as a mechanism which enables these pupae to conserve water[5,6]. Indeed, it has been shown that at 25° C the spiracular valves are open no more than 5 to 8 per cent of the entire respiratory cycle[7], and at lower temperatures they must open still less. This enables the pupae to conserve water.

How do the spiracles behave at the sub-zero temperatures experienced by the pupae? Does the co-ordinated neuromuscular activity, necessary for discontinuous respiration, persist? If discontinuous respiration does not continue, are there other adaptations which limit pupal water loss?

To answer these questions, a diapausing *Hyalophora cecropia* pupa was placed in a constant temperature chamber which could be adjusted to temperatures between +20° and −20° C ± 0·5°. Intratracheal pressure and movements of one spiracular valve were recorded simultaneously at five degree intervals. Pupal water loss was determined at −2° and −16° C.

The pupa was connected to a pressure transducer with a polyethylene cannula, and intratracheal pressure changes were recorded automatically[7,8]. The pupal tracheal system could be opened to atmospheric pressure by remote control, using a system of solenoid control valves.

To record spiracular movements, we employed a method described recently[4]. The cuticular covering of the fourth right abdominal spiracle was removed to expose the spiracular valve. The exposed valve was then covered with a transparent plastic window to prevent the valve from drying out. Movements of the valve were observed through an ocular micrometer and recorded. Gas exchange through the spiracle was blocked permanently by the window. Gas exchange, however, occurred through the corresponding spiracle on the left side; the behaviour of such paired spiracles has been shown to be co-ordinated[7].

In the experimental conditions pupae were cooled slowly (≤ 0·5°/min). Between −5° and −10° C the pupae froze, and when cut with a knife they appeared to be solid throughout.

At −5° C cyclical pressure changes, microcycles, and intratracheal vacuums, characteristic of discontinuous respiration, persisted throughout 286 h of continuous recording. The frequency of valve movements decreased from 32/min at +20° to 1/min at 0° C; similar results have been reported for Cecropia and for several other insects (refs. 9–11, and Brockway and Schneiderman, in preparation). At −5° C movements occurred from one every 2 min to one an hour; however, there were intervals of several hours during which no movements were observed. Most valve movements occurred slowly at −5° C, but nonetheless the changed position of the spiracular valve could be recorded easily. At some ambient temperature between −5° and −10° C discontinuous respiration ceased; the valves closed and they remained closed thereafter when the temperature was decreased to $-15°$ and $-20°$ C. The valves were not hermetically sealed, however, because intratracheal pressure remained atmospheric throughout 270 h of continuous recording at $-15°$ and $-20°$ C. Other data show that oxygen uptake by frozen Cecropia pupae continues even at sub-zero temperatures ($<0{\cdot}1$ $\text{mm}^3/\text{g}^{-1}$ h^{-1} at approximately $-12°$ C)[12]. Had the valves been hermetically sealed the intratracheal pressure records would have indicated steadily decreasing intratracheal pressure as a result of the removal of tracheal oxygen by metabolizing tissues.

The results up to this point show that at $-5°$ C: (1) spiracular valves move; (2) the cyclical nature of the spiracular movements indicates that the responses to oxygen and carbon dioxide persist; (3) the occurrence of flutter and the responses to oxygen indicate that neuromuscular co-ordination persists.

Additional evidence that the spiracular apparatus continues to respond to intratracheal gas changes at $-5°$ C comes from experiments in which the tracheal system was perfused with oxygen and carbon dioxide in various concentrations by a method previously described[4]. At $+25°$ C, perfusion with 7 per cent carbon dioxide in air causes the spiracles to open; perfusion with 3 per cent oxygen in nitrogen causes them to open as a result of anoxia; 8 per cent oxygen plus nitrogen causes them to close. Perfusing the tracheal system of a pupa at $-5°$ C with a mixture of 20 per cent carbon dioxide in air or with 0·5 per cent oxygen in nitrogen caused the spiracular valves to open; the valves could then be closed by perfusing the tracheal system with air. At $-10°$ C the valves failed to open in response to intratracheal perfusions of up to 50 per cent carbon dioxide. Moreover, if the valves were open at $-10°$ C then they could not be made to close by perfusions of up to 100 per cent oxygen. This is shown by the results of the following experiment. The ambient temperature was lowered from $-5°$ to $-10°$ C while the valves were in an open position. After the pupa had equilibrated at $-10°$ C for 12 h air was perfused intratracheally. The valves remained open and did not constrict even when 100 per cent oxygen was perfused through the tracheal system. Seven hours after the ambient temperature was increased again to $-5°$ C, however, valves did constrict in response to an air perfusion.

Further evidence that at temperatures below $-5°$ C the spiracular apparatus does not respond to carbon dioxide comes from studies of pupal water loss at $-2°$ and $-16°$ C. At the end of one week in air, at about 0 per cent relative humidity at $-2°$ and $-16°$ C, two groups of pupae lost an average of $1{\cdot}29 \pm 0{\cdot}56$ (*S.D.*) and $0{\cdot}65 \pm 0{\cdot}29$ per cent of their original weights, respectively. The pupae, which had been kept at $-16°$ C, were warmed to room temperature, exposed to a mixture of 20 per cent carbon dioxide in air to open all spiracular valves, and then, with the valves still partly open, were chilled again at $-16°$ C for 1 week with the spiracles open. The average weight loss of the pupae with partly open spiracles at $-16°$ C was $1{\cdot}44 \pm 0{\cdot}65$ per cent. This weight loss was more than twice the average weight loss in air at $-16°$ C when the spiracles were constricted. A second group of pupae, which in air at $-16°$ C had lost an average of $0{\cdot}40 \pm 0{\cdot}20$ per cent of their original weights, was exposed to a mixture of 20 per cent carbon dioxide in air at $-16°$ C. After 1 week the average weight loss was $0{\cdot}22 \pm 0{\cdot}13$ per cent of the average weights before the exposure to 20 per cent carbon dioxide. Apparently at $-16°$ C the spiracles did not respond to carbon dioxide.

These experiments show that down to at least $-5°$ C (but not at $-10°$ C) diapausing Cecropia pupae continue to respire discontinuously (thus conserving water), and their spiracular muscles and some nerves remain functional. The spiracular muscle continues to respond to carbon dioxide, the central nervous system continues to respond to oxygen, and at least paired spiracles remain co-ordinated. At some temperature between $-5°$ and $-10°$ C pupae freeze in our experimental conditions. Determinations of pupal water loss at $-16°$ C indicate that normally spiracular valves freeze in a constricted position but intratracheal pressure records show that valves are not hermetically sealed. At temperatures below $-5°$ C gas exchange must occur by simple diffusion past constricted valves; thus water loss is kept low. The spiracles continue to serve the insect even at very low temperatures at which there is no nervous or muscular control of spiracular function because conditions in nature normally ensure that the spiracular valves freeze in the constricted position.

We thank Dr R. K. Josephson, Dr K. Madhavan, Dr N. G. Patel and Dr F. Sehnal for helpful comments. This research was supported by a research grant from the US Public Health Service.

Possibility of Investigating Movement in a Group of Ants by the Mössbauer Effect

THE probability of recoil-free resonance absorption of gamma-quanta depends on the relative velocities of source and absorber[1,2]. The velocity distribution of moving absorbers can be deduced from the form of the resonance line. In principle this is possible when the velocities are within the range of the Mössbauer spectrometer. In practice they should have a resonance width close to that of stationary absorbers because otherwise their line can become so broad as to cause considerable difficulty[3].

We have used the Mössbauer effect to investigate movement in a group of ants. These are large enough to carry measurable amounts of a resonance absorbing substance, and small enough so that a considerable number of them can be placed between the source of radiation and the detector; this is necessary for statistical reliability.

We used a Mössbauer spectrometer with a source of radiation of constant velocity. The velocity was adjusted smoothly from 0 to 40 mm/sec by means of a 10-rotation helical potentiometer. The counts for positive and negative velocities are collected in separate counters for every cycle of movement of the source. Stannic oxide was used as a resonance absorber. We summed the counts from those velocities which were equal in absolute value and differed only in their sign. The effect observed at room temperature can be expressed as $\varepsilon_0 = \dfrac{N_\infty - N_0}{N_\infty}$ where N_0 is the number of counts at zero velocity, and N_∞ is the number of counts far from resonance and which goes up 20 per cent to 30 per cent, depending on the radio-

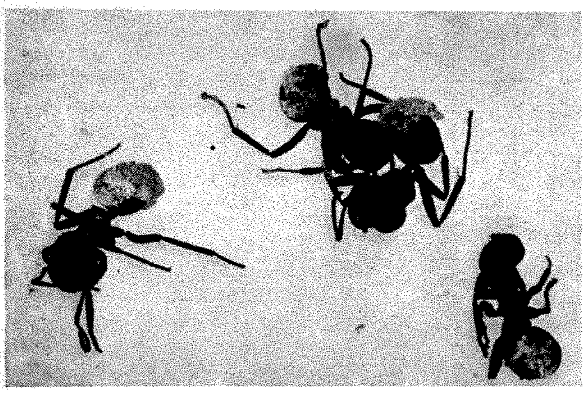

Fig. 1. Photograph of ant "marked" with stannic oxide.

active purity of the source. The relatively small temperature dependence of ε_0 (refs. 4 and 5) is a particularly valuable property of stannic oxide. Its chemical inertness, its stability in air, and the fact that it takes in no moisture and does not decompose, are also very important. The gamma-quanta, with 23·8 keV energy, were detected with a thallium doped crystal of sodium iodide 1 mm thick, in front of which was placed a palladium filter to eliminate X-rays.

We used *Formica pratensis*, De Geer, an ant which is widespread in Bulgaria. Worker ants, which we used, can reach 9 to 11 mm in length. They move quickly and are aggressive; when in danger they stand up and bend their abdomen, from which they eject formic acid.

The respiratory system, as in all insects, consists of tracheae, which open on to the lower part of the abdomen and also partly onto the thorax. The stigmae can open and close, or be permanently open[6], depending on the proportion of oxygen and carbon dioxide in the air. The abdomen makes "telescopic" movements, during which the individual segments merge into one another. The abdomen can also expand slightly, inflate and shrink. Ants are never completely still. The body, and in particular the abdomen, vibrates irrespective of respiratory movements. Metabolism and the demand for oxygen increase when the temperature deviates from the optimum[6].

The upper part of the abdomen of each ant was pasted with "BΦ 2" glue (made in USSR), and finely ground stannic oxide was immediately sprayed onto the glue. The marked ants (Fig. 1) were placed in an insectarium with mesh walls which ensured aeration without which ants would die in a few minutes because the atmosphere was saturated with glue vapour.

Fifty ants were placed in several aluminium cuvettes with mesh bases, stacked on top of each other with 2·3 ants/cm^2. When placed in the cuvette the ants spray formic acid and the scent only disappeared after air had been blown through the cuvette. The cuvettes were placed in a double-walled metal vessel, with water at a pre-determined temperature between the walls. A stream of air, which was previously moistened (100 per cent by passing it through water at the temperature of the thermostat), was passed through the cylinder formed by the cuvettes. The air input was measured by an anemometer. To kill the ants, to measure the "natural width" of the absorber, the water was replaced by ether. The ants stopped moving in 1 to 2 min.

In our experiments so far we have only studied the influence of temperature and, partly, of the air input, on the shape of the resonance line. Changes in temperature affect the band width considerably (Fig. 2). For a better comparison of the spectra on the abscissa of the graph in Fig. 2 the value of $\varepsilon_v/\varepsilon_0$ has been included, where ε_v is the effect at velocity v. Fig. 3 shows the dependence of the semi-width resonance line on the temperature band for two series of tests. In both cases ants were taken from the same nest, but on different dates. The dot placed above zero temperature refers to dead ants, and in this case is equal to "frozen". Attention should be drawn to the fact that for the broadening of the resonance absorption line only that component of the speed of the separate "absorbers" in the direction of the beam of gamma-photons is important.

With increasing temperature the dots characteristically begin to fluctuate outside the limits of the most probable deviation and the instruments do not seem to work in a stable manner. The greater the temperature the stronger is the effect (Fig. 2). After the death of the ants the instruments become "stable" at once. We believe that this is caused by ants which crawl at the higher temperature, and change the geometry of the experiment. Fluctuations cease when the value is taken from several counts for each velocity, alternated with measurements at zero velocity; the effect is determined by the difference of the count rates summed for each group of measurements. This is how the resonance line shown on Fig. 4 was obtained. Obviously the best method for further measurements would be to work with a source the velocity of which changed triangularly with time with the spectrum displayed on a multi-channel analyser[1,2].

Resonance curves for ants at the same temperature, but with a constant inflow of air (cm^3/min) as well as with no inflow of air, are given on Fig. 5. In the second case there is a slight expansion, probably caused by the in-

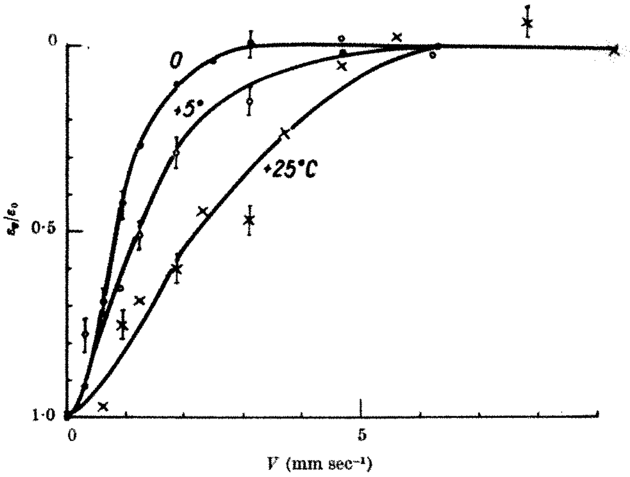

Fig. 2. Curves of resonance absorption of ants at various temperatures. The "0" curve refers to dead ants after the completion of measurements. 270 ants were killed.

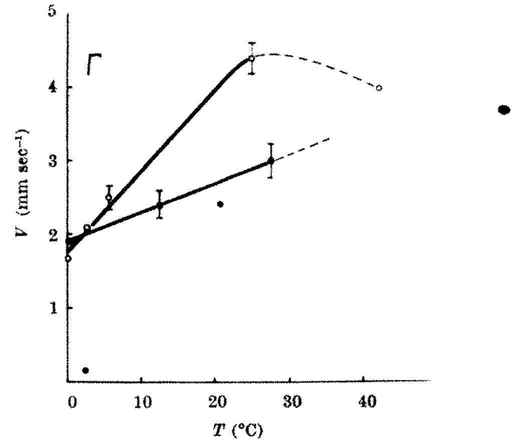

Fig. 3. Dependence of the semi-width of absorption line for ants at various temperatures. The dots at 0° C correspond to dead ants. The two sets of measurements were made on: upper curve, May 9, 1966, 270 ants; lower curve, June 24, 1966, 450 ants.

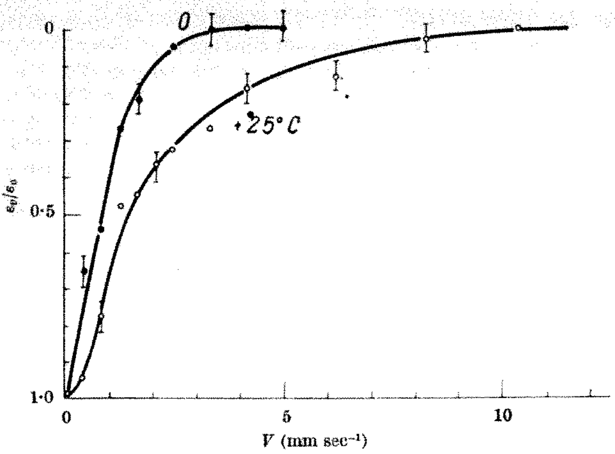

Fig. 4. Curves for resonance absorption. Ten measurements of 20 sec at each speed, alternating with the same number of measurements at zero velocity, were made. The lower curve refers to ants at +25° C, and for comparison the upper curve shows the resonance absorption for the same ants when dead. 450 ants were used.

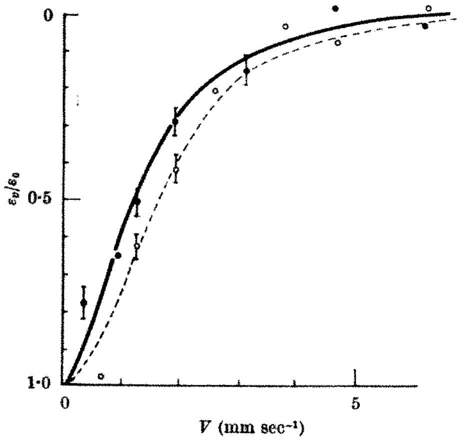

Fig. 5. Curves for resonance absorption of ants at +5·5° C. Upper curve in an air stream of 600 cm³/sec, and lower curve with no air stream.

crease in periodicity cycles of the breathing movements. When measurement is continuous, for example, for more than one or two days, and in particular at high temperatures (over 25° C), the ants begin to die, making a "background" or "sediment" of immobile filters.

Broadening of resonance should be regarded as a consequence of breathing movements and flickering of the abdomen. Ants move very quickly, up to 3–5 cm/sec, and the result is out of the scope of our measurement. The resonance absorption of these velocities is too weak and very good statistics are necessary to outline the resonance line.

We think that these first results show that the Mössbauer effect can be used to measure changes in the reactions of organisms under the influence of various factors. The laws governing the movement of individual insects can be tested by other methods, for example, still and cine photography, but the Mössbauer effect makes it possible to examine changes in the average quadratic speed of a large number of insects. Many measurements can be made in a short time, and the behaviour of organisms from various taxa can be compared.

CYTOLOGY

Changes in Membrane Impedance associated with a Cortical Contraction in the Egg of *Xenopus laevis*

Attention has recently been drawn to the concept of the cell membrane as a transducer of external stimuli, mediating between environmental effectors and cytoplasmic responses by altering the surface potential (refs. 1 and 2, and our own results which are in preparation). Alteration of the potential profile through the membrane,

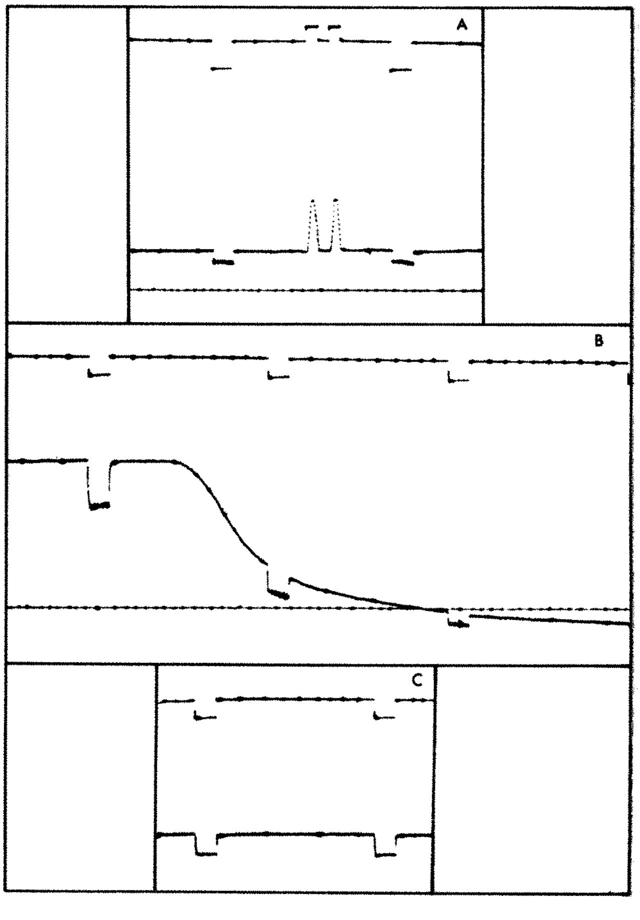

Fig. 1. Changes in electrical potential and cell membrane impedance in a two cell embryo preceding contraction in response to local application of ribonuclease to the animal pole, in the presence of divalent cations. Voltage pulses for current determination appear on the uppermost trace; those for resistance measurements appear as downward displacements of the middle trace while the lowest trace (not shown in *C*) is a constant reference potential. Time runs from left to right in each insert. Speed: normal, 0·5 cm/sec. *A*, 1 mV calibration on the current trace and 10 mV calibration in 1 mV increments on the resistance trace prior to penetration of the egg. *B*, After penetration of both electrodes, the resistance pulse was seen to be larger. Immediately before the addition of RNase, membrane impedance was calculated to be 420 kΩ and the measured potential (–) 20 mV. On adding RNase both fell steeply. The potential became positive (+12 mV) and the impedance was reduced to a few kΩ. Contraction occurred. *C*, Spontaneous recovery after a further 10 min partially restored potential and impedance to (–) 8 mV and 120 kΩ, respectively. The contraction was subsequently seen to have relaxed. Note: current amplifier gain was altered between *A* and *B*.

resulting from a change in electrostatic surface potential caused by changes in external ionic strength, adsorption of polyions or the close approach of cell surfaces, could lead to cytoplasmic reactions[1]. Changes in membrane field might affect the conformation of membrane macromolecules, leading to the presentation of new groups at the cytoplasmic interface. Alternatively, changes in permeability of the membrane might follow conformational changes, or else might occur in their absence. Any of these mechanisms could provide the cytoplasm with information about the external environment on which it might act accordingly. The possibility of co-operative phenomena in membranes, envisaged by Changeux and his colleagues[3,4], is of great interest in this respect,

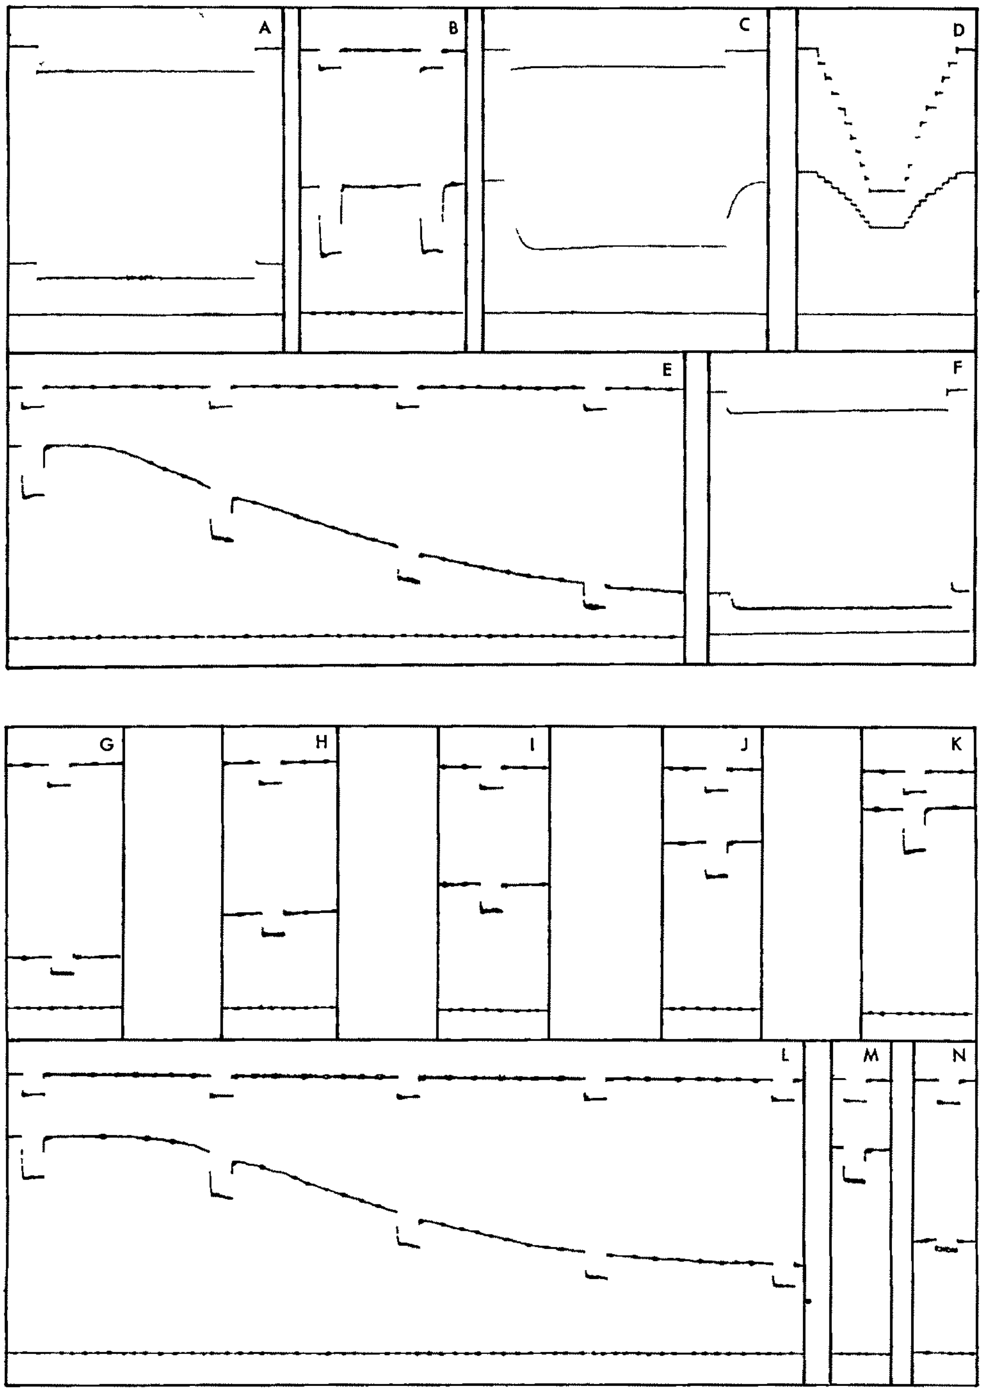

Fig. 2. Electrical potential and impedance changes in a four cell embryo without contractile response, caused by the action of local application of ribonuclease to the cell surface, in medium free of divalent cations. Voltage pulses for current measurement are recorded on the uppermost trace, while the lowest trace is a constant reference potential. Time runs from left to right in each insert. Speed: normal, 0.5 cm/sec, fast 5 cm/sec. *A*, Fast pulse taken with both electrodes outside the cell. *B*, On penetration with both electrodes, a negative potential and increased resistance were recorded. Membrane impedance was calculated to be 430 kΩ. *C*, A fast pulse showed capacitative rise and fall. *D*, 10 mV calibration in 1 mV steps. *E*, A few minutes later the potential had increased. Local addition of 1.0 per cent RNase at the animal pole of the egg resulted in a fall of the potential to zero and the impedance was reduced to a few kΩ. No contraction occurred. *F*, A fast pulse taken immediately after *E* was seen to have lost its capacitative shape almost completely (compare *C*). *G* to *K*, Spontaneous recovery of both potential and impedance over a period of about 6.5 min. The former rose to its original value and the latter recovered to 360 kΩ. *L*, A second application of RNase sent the potential and impedance down to (–) 9 mV and 59 kΩ respectively. No contraction took place. *M*, Spontaneous recovery after 6 min. Potential, (–) 18 mV, impedance, 270 kΩ. *N*, After electrode withdrawal the pulse was reduced and the zero had shifted about 10 mV in a positive direction.

especially because the stimulus for co-operative change might be a change in membrane electrostatic field[5]

A new system for experimental investigation of these concepts involves a cortical contractile response by the eggs and early cleavage stages of *Xenopus laevis* to surface-adsorbed polyions and ionic detergents (results in preparation) When 0·1 per cent solutions of poly-L-lysine of molecular weight 2,600, 50,000 or 250,000, or ribonuclease, both of which are polycationic for a wide *p*H range, were applied locally by means of a fine pipette near the surface membrane of fertilized eggs or early cleavage stages, from which the jelly and vitelline membrane had been removed, a localized non-propagated contraction occurred after a delay of 1–2 min in normal Steinberg's medium The same phenomenon followed similar application of the cationic detergent hexadecyl trimethylammonium bromide at 0·5 mmolar and also the anion detergent sodium dodecyl sulphate at 1·0 mmolar Nor ionic detergents 'Triton *X*-100' and 'Pluronic *F*68' wer ineffective even at 1 per cent Electron microscopy regions which had been thus treated shows that the su face membrane is thrown into extensive folds as a resu of contraction of the subjacent cortex, which is chara terized in the animal pole by local accumulation of pi ment granules There is no evidence that the membra undergoes active contraction

Reversible relaxation of the contraction induced b poly-L-lysine was obtained, with a few minutes' delay, b bathing contracted eggs in 0·1 per cent sodium poly- glutamate (molecular weight 68,000) or sodium hepari at around neutral *p*H Replacement by normal Stein berg's medium even after 30 min resulted in local r

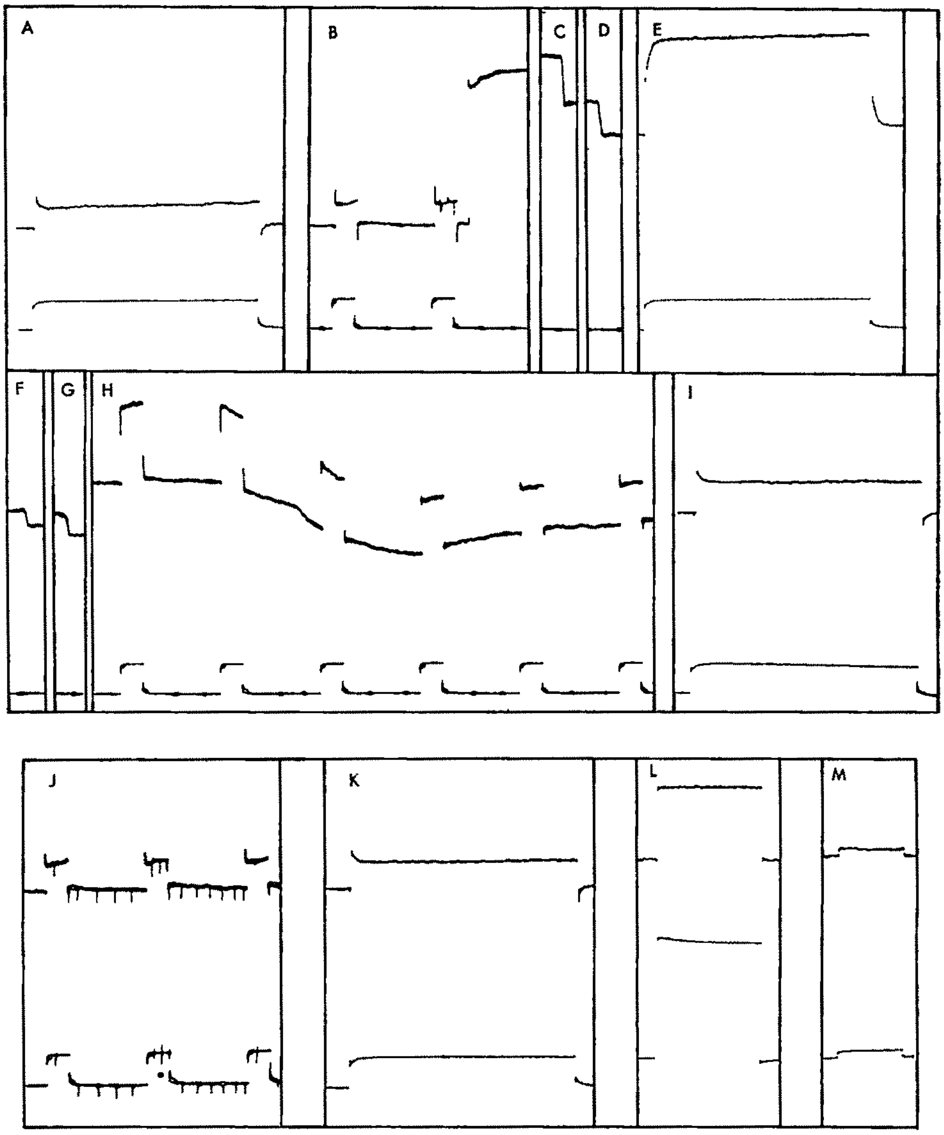

Fig 3 Changes in electrical potential and membrane impedance associated with the action of polylysine on a two cell stage embryo, first in the absence of divalent cations and then after their addition The upper trace records potential and the periodic upward displacements give resistance data The lower trace records current pulses Time runs from left to right in each insert Speed normal 0·5 cm/sec, fast, 5 cm/sec *A*, Square pulse before penetration of recording electrode *B*, Penetration of recording electrode A negative potential of (−) 22 mV was recorded *C* and *D*, Potential trace was shifted to accommodate impedance pulses *E* Capacitative fast pulse membrane impedance was calculated to be 320 $k\Omega$ *F* and *G* Potential trace shifted again during flushing out of the electrode bath with divalent cation-free Steinberg's medium The measured potential fell 6 mV *H*, After washing for 6 min the membrane impedance had fallen to 210 $k\Omega$ though the pulse was still capacitative 0·1 per cent polylysine was added locally to a region of the animal pole between the first and second pulse of this insert The potential underwent a temporary change of (+) 10 mV, but the impedance fell and continued falling to a few $k\Omega$ There was no sign of contraction in the egg *I*, A fast pulse showed negligible capacitance and little impedance *J*, Three min after the addition of polylysine the electrode bath was replenished with ordinary Steinberg's medium Drop-wise addition produced 'spikes" on the record *K*, Without further change in electrical characteristics of the membrane (compare *I*) contraction occurred within 1 min of adding Steinberg's medium *L*, 10 mV calibration. *M*, 1 mV calibration

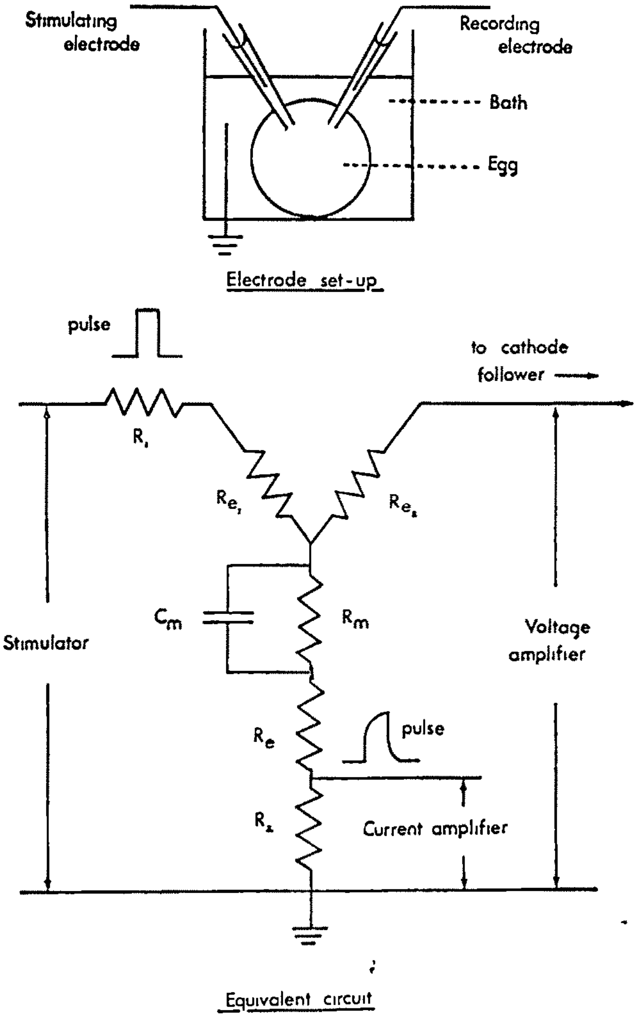

Fig 4 The upper diagram shows the electrode arrangement used in experiments on *Xenopus laevis* eggs and the lower diagram gives an outline of the circuit R_{e_1} is the resistance of the stimulating electrode, R_{e_2} the resistance of the recording electrode and R_e that of the indifferent electrode R_m is the resistance of the cell membrane and C_m its capacitance R_1 is the output resistance of the stimulator, 10^9 Ω R_2 is a resistance of 10^5 Ω across which current is measured Characteristic pulse profiles before and after the current passes through the cell membrane are indicated

contraction of the fully relaxed region, suggesting that the polycation was not eluted from the cell surface by the polyanion Exposure to 0 5–2 0 molar sodium chloride caused relaxation, probably without removal of bound polycation

Using a recording technique which employs two intracellular glass microelectrodes[8] filled with 3 molar potassium chloride (Fig 4), untreated two or four cell stages were found to have impedances (R_m) in the range 250 to 450 kΩ If the surface is taken to be 0 04 cm², an R_m of 350 kΩ would give a unit area resistance of 14 kΩ cm² Recorded potentials which were not corrected for changes in microelectrode tip potential inside the cell were usually between – 20 and – 30 mV in normal Steinberg's solution Potential and impedance vary during early cleavages (unpublished results of Palmer) and for this reason care was taken to avoid measurements on dividing cells Following local applications of ribonuclease near the cell surface, the potential which was measured fell and sometimes reversed to positive values, while the membrane impedance invariably fell to below 50 kΩ within a few seconds Visible contraction followed in a minute or two Poly-L-lysine also reduced the impedance, but the potential underwent a temporary change followed by a return to normal Rapid recovery of impedance and potential did not occur after poly-L-lysine treatment alone, but spontaneous recovery accompanied by relaxation followed about 8 min after ribonuclease treatment (Fig 1) The addition of 0 1 per cent poly-L-glutamate caused slow relaxation of a region which was previously contracted by poly-L-lysine during the course of several minutes, and this was preceded by restoration of membrane impedance but with little change in the potential The polyanion alone had almost no effect on the impedance or potential of untreated cells.

In the absence of external divalent cations with or without 3 mmolar di-sodium ethylene diaminetetraacetate (EDTA), neither ribonuclease nor poly-L-lysine induced contraction, although the membrane impedance fell as before and the potential changed characteristically (Fig 2) Addition of normal Steinberg's medium containing 0 34 mmolar Ca^{++} and 0 83 mmolar Mg^{++} was attended, however, by a rapid contraction at the site of polyion application without further change in membrane impedance or potential (Fig 3)

The events leading to contraction seem to fall into a sequence (1) a change in the membrane in response to adsorbed charged molecules, (2) ion movements in response to changed membrane properties, and (3) cytoplasmic contraction, the mechanism of which is not considered in any detail here. From the work of Nevo, de Vries and Katchalsky[7] there is good evidence that poly-L-lysine binds to the outer surface of the red cell without penetrating the membrane Electron microscopic examination of eggs which were treated with poly-L-lysine reveals a thick dense layer, 200–300 Å on the surface, which is not present in untreated eggs This layer probably represents poly-L-lysine adsorbed to the surface coat Ionic detergents could adsorb at the lipid–water interface within the membrane Adsorption of charged molecules which alter the surface potential is therefore believed to be the first step in the sequence A fall in membrane impedance followed immediately, indicating increased membrane permeability, though to which ions is uncertain The direction of the accompanying potential change after ribonuclease treatment suggests increased sodium permeability No cortical contraction follows unless divalent cations are present in the external medium Passage of these ions into the cytoplasm may be directly responsible for activating a contractile apparatus in the cortex, but this has not yet been directly demonstrated An alternative explanation may be that divalent cations are released from combining sites on the inner surface of the membrane in response to changes in the membrane as a result of the adsorption of charged molecules in the presence of external divalent cations

The membrane changes preceding relaxation could be initiated by restoration of the surface potential Salt would act thus, by reducing the positive surface potential caused by adsorbed polycation towards zero by virtue of increased ionic strength Relaxation in Steinberg's medium, which contains 0 06 molar sodium chloride, following contraction which was induced by ribonuclease, is probably caused by salt elution of the protein which is less strongly electrostatically bound than poly-L-lysine The relaxation induced by polyanions can be interpreted as a result of their reversible bonding to surface-bound polycations, thus reducing the net positive charge and potential near the cell surface Sequestering of divalent cations in solution by polyanions could play some part in the process, though divalent cation removal *per se* would increase membrane permeability and cannot explain the increased membrane impedance which precedes relaxation

In conclusion, the observations which have been made may be tentatively interpreted as follows An increased negative or positive surface potential triggers a change in the state of the membrane which is characterized by a fall in impedance which is reversed on restoration of the surface potential towards a smaller absolute value The cytoplasmic contraction which is dependent on divalent cations and which follows reduction of membrane impedance could reflect an influx of divalent cations

It is tempting to speculate on the apparently analogous events in muscle where release of calcium from the sarcoplasmic reticulum in response to membrane depolarization[10] is believed to initiate myofibrillar contraction Both systems could involve movements of divalent cations through a membrane the state of permeability of which is a function of its electric field Cellular motile responses of *Amoeba proteus* to polyions and salts have been examined with the microelectrode technique and the results, which also suggest that changes in potential of the surface membrane can control cytoplasmic events, will be reported in detail elsewhere (results in preparation)

MICROBIOLOGY

Skin Heterogenizing Virus

WE have reported previously[1-3] that some murine transplantable tumours contain an agent capable of inducing a strong transplantation antigen in the skin of mice with tumours The skin was regularly rejected both in syngeneic grafting and in autotransplantation We call this phenomenon heterogenization or allogenization of skin under the effect of tumour[1-3] Skin grafts taken from mice which had rejected skin grafts obtained from the tumour-bearing donors were also rejected in syngeneic transplantation We also demonstrated the transfer of skin heterogenization by means of skin grafting in eight successive passages

Heterogenization of the skin has now been obtained by injecting tumour homogenate Our experimental data show that the skin heterogenizing agent is a new virus, possibly the first representative of a new oligocystronal group of viruses

In our experiments, sarcoma *K*-237 of *C57BL/6 Jax* mice was used The tumour strain and the experimental technique were partially described before[1,2]

For homogenates, the tumour pieces were cleaned from the necrotic areas and ground with glass for 30 min at 4° C The homogenous mass was then diluted to 10 per cent with Hanks solution (*p*H 7 2) The basic material used throughout the experiments was the supernatant fluid obtained after 10 per cent homogenate had been centrifuged for 30 min at 1,500*g* (later called supernatant 1) For differential centrifugation the following speeds were used stage 1, 3,000*g* or 10,000*g*; stage 2, 80,000*g* or 130,000*g* The sediments were resuspended with the initial volume of Hanks solution, the supernatants were used for further centrifugation

To study the thermostability, supernatant 1 was heated for 30 min at different temperatures in a water bath or kept at −20° C or −70° C for 24 h

Ether sensitivity was determined by adding an equal part of diethyl ether and incubating at 4° C overnight The ether was then removed, and the remainder was evaporated in a Petri dish at room temperature

The ten-fold dilutions, using Hanks solution, were used for agent dose titration The presence of skin heterogenizing agent in different materials was tested as follows Donor mice, adult *C57BL/6 Jax* females, received the materials in 0 5 ml volumes, both subcutaneously and intraperitoneally, in a total volume of 1 ml to each mouse The skin of these mice was checked by syngeneic grafting, carried out 3 weeks after inoculation

The presence of the virus in the sera and lymphoid organs of the tumour-bearing mice was also investigated For this purpose, donor mice were injected with 0 15 ml of pooled serum both intraperitoneally and intravenously. The same injection route was used for a mixture of spleen and lymph nodes cells, the total amount being 250×10^6 cells/mouse The control materials were injected in the same way The establishment of heterogenization was tested

It can be seen from Table 1 that the skin heterogenizing agent is present both in tumour homogenates and in lymphoid cells of tumour-bearing mice, but not in the pooled serum where it is possibly neutralized by antibodies The agent is etheroresistant, inactivated at 60° C and only partially sedimented at 130,000*g* Furthermore, only partial sedimentation was obtained even after centrifugation at 226,000*g* for 6 h The properties of the agent indicate that it resembles a very small virus which is resistant to ether The virus dose in tumour supernatant 1 was higher than 10^{10} particles/ml of the heterogenization producing mature virus (not indicated in Table 1)

Table 1 PROPERTIES OF THE SKIN HETEROGENIZING VIRUS

C57BL/6J donors inoculated with	Rejection of syngeneic skin grafts in normal recipients
Pieces of the tumours, *K*-237, used for preparation of homogenates	24/24*
Serum pool from tumour-bearing mice	0/4
Mixture of lymphoid organ cells from tumour-bearing mice	8/8
Supernatant 1	28/32
Supernatant 1 heated for 30 min at 45° C	13/16
Supernatant 1 heated for 30 min at 60° C	1/11
Supernatant 1 frozen for 24 h at −20° C	8/8
Supernatant 1 frozen for 24 h at −70° C	8/8
Supernatant 1 treated with ether	8/8
Supernatant after centrifugation of supernatant 1 for 30 min at 3,000*g* or 10,000*g*	26/29
Sediment after centrifugation of supernatant 1 for 30 min at 3,000*g* or 10,000*g*	0/4
Supernatant after centrifugation of supernatant 1 for 60 min at 130 000*g*	6/7
Sediment after centrifugation of supernatant 1 for 60 min at 130,000*g*	3/7

* Numerator, number of mice with grafts rejected, denominator, total number of recipients

The possibility of specific virus neutralization was investigated in the following experiment The donors of immune serum were *C57BL/6 Jax* female mice which rejected heterogenized skin A month after the average end-point of rejection, these mice were injected with 1 ml of supernatant 1 once a week for 3 weeks

Blood was taken from the orbital sinus of donor mice 1 week after the last injection The pooled serum, from six mice, was heated at 56° C for 1 h in a water bath; the sera of the control normal *C57BL/6 Jax* mice and *BALB/c* mice was prepared in the same way The sera were diluted 1 2, 1 20, 1 200 and 1 2,000 The supernatant served as a source of virus (infectious titre being higher than 10^{10}) It was admixed with equal volumes of corresponding dilutions of tested sera and incubated at

Fig. 5. Type *a* particle (× c. 620,370).

37° C for 1 h. Then the groups of *C57BL/6 Jax* mice were inoculated and the establishment of heterogenization was tested as usual.

The data in Table 2 show that the specific neutralization of skin heterogenizing virus occurred. The immune sera employed here must contain large amounts of neutralizing antibody because the virus dose was higher than 10^{10}.

Table 2. NEUTRALIZATION OF THE SKIN HETEROGENIZING VIRUS

Donors of sera	Reciprocal to serum dilution 2	20	200	2,000
C57BL/6 Jax immune	0/8*	0/5	3/6	4/5
C57BL/6 Jax normal	4/6	4/4	4/4	—
BALB/c normal	6/6	6/6	6/6	—
Hanks solution	8/8	—	—	—

* As in Table 1.

Passage of heterogenization from one mouse to another by skin grafting showed that not only tumour cells but also the skin cells produced the mature virus. The persistence of "new" transplantation antigen, as well as the virus producing capacity of skin cells, was maintained in the infected mice for more than 4 months. The virus was also present in skin homogenates free of living cells.

The simultaneous induction of strong transplantation antigen, and the production of virus in large quantities, indicates a quite original mechanism of interaction between virus and cell in this experimental system. A quantitative study of virus behaviour is now in progress. The *C57BL/6 Jax* and *BALB/c* mice, which were inoculated by different routes with the supernatant 1 when they were born, had not produced any noticeable pathological changes after 8 months of observation.

A resuspended pellet from supernatant 1, after centrifugation at 80,000*g* for 1 h, was used for electron microscopy. The preparation was contrasted with 2–4 per cent phosphotungsten sodium solution *p*H 7·0. The electron microscope, *JEM*-7, was used at instrumental magnifications of × 50,000, × 70,000 and × 100,000.

Two kinds of complete, hollow (empty) virus-like particles were found in the preparations, and were designated as type *a* and *b* particles (see Figs. 1–5). The particles exhibit cubic symmetry of the icosahedral type.

The diameter of type *a* particles was 165 to 175 Å, the thickness of the walls of the hollow particles being not more than 30 Å. The diameter of the internal cavity of these particles was about 100–115 Å and the volume was about 1,000,000 $Å^3$. The external diameter of type *b* particles was 75 to 85 Å, the thickness of the walls of the hollow particles was about 20 Å, the internal cavity diameter was 35–45 Å, and the volume was about 60,000 $Å^3$ (Fig. 6).

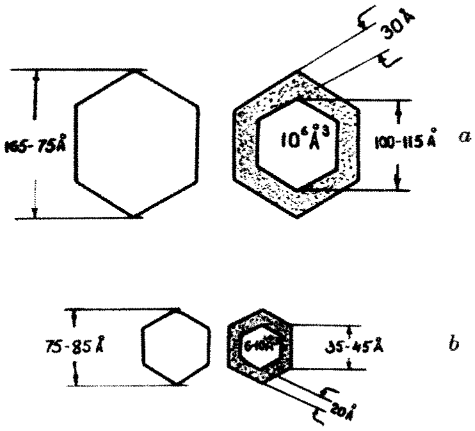

Fig. 6. Viral particles scheme.

These results confirm our previous suggestion that skin heterogenization is produced by a virus[1-3]. This virus seems to be etheroresistant and very small. It reproduces in the tumour and skin cells, and is present at least in the lymphatic organs of tumour-bearing animals. The only evident sign of infection is the induction of new antigen in the skin, which makes it incompatible in autologous and syngeneic grafting.

In this respect it seems important that virus particles were found in sarcoma *K*-237 homogenate with the help of electron microscopy. In view of the high magnification employed, these particles may be considered to be present in high concentrations (see Fig. 1). This fact correlates in an indirect way with the high biological titre of the heterogenizing virus in the homogenate.

Previously one of us[4-6] emphasized that "cell heterogenization in respect of the whole organism" is a basic feature of interaction between cell and virus. There may be a whole world of viruses which cause the diseases based on the cell heterogenization phenomenon. Some of these diseases are referred to as autoimmune rheumatic fever, the nature of others, such as pemphigus and psoriasis, is not known very well.

Possibly this skin heterogenizing virus is the first representative of a large group of viruses which are inductors of autoimmune diseases or syngeneic tissue compatibility conflicts. These viruses are preliminarily designated as rheumoviruses.

GENERAL

Holographic Model of Temporal Recall

How do we manage to recognize immediately, and to recall without effort, familiar words, sentences and other behavioural sequences? I suggest that we employ a system which is the temporal analogue of optical holography[1-3]. The analogy between holography and visual memory has already attracted attention in the literature, but this is not quite the thought that I shall pursue here; rather I shall consider the time dimension, because any perceptual event must certainly be associated with cerebral happenings which are extended not only in space but in time. If a system of this kind were indeed used by the brain, not only would some familiar phenomena of perception be naturally explained, but the cells or cell clusters responsible for laying down sensory information should have a certain property which might be accessible to experimental test.

The system which I have in mind is most easily described with the aid of a concrete example. Imagine a bank of resonators, rather like the strings of a piano. Their resonant frequencies ν_k are supposed to be evenly distributed over a certain frequency band, with a spacing equal to μ, and the bandwidth of each resonator will be assumed equal to the same constant μ. Each resonator is supposed to be coupled to the input signal $f(t)$ according to the equation

$$\ddot{x}_k + (4\pi\mu)\dot{x}_k + 4\pi^2(\mu^2 + \nu_k^2)x_k = A_k f(t)$$

where x_k denotes the displacement of the kth resonator, and A_k is a coupling constant. Then it can be shown that the total response of the bank, conveniently defined as

$$g(t) = \sum_k(\dot{x}_k + 2\pi\mu x_k)$$

will be proportional to $f(t)$ provided (*a*) that the coupling coefficients A_k are all equal; (*b*) that $f(t)$ contains no frequencies lying outside the range of the bank and (*c*) that μ is sufficiently small—that the resonators are sufficiently densely distributed over the frequency range.

I now imagine that after the passage of a signal $f(t)$, the coupling constant of each resonator is capable of being altered by an amount proportional to the work recently done on it by the signal, that is,

$$\Delta A_k = \lambda\int_{-\infty}^{0} f(t)\dot{x}_k(t)e^{4\pi\mu t}\mathrm{d}t$$

where the quantity λ is supposed to be the same for each resonator. If the signal consisted of a pulse $f_1(t)$ followed immediately by another signal $f_2(t)$, then it can be shown that if the coupling constants are subsequently adjusted as shown, a later input of the same pulse will immediately evoke a response $g_2(t)$ proportional to $f_2(t)$. This phenomenon is the mathematical analogue of the following holographic observation: a collimated laser beam is split into two parts; one is directly incident on a photographic plate, and the other falls on an object, the light from which is also incident on the plate. The plate is developed and replaced by its positive print, the hologram; the object is removed, and the hologram is illuminated with the first part of the same laser beam. An observer looking through the hologram then beholds the absent object in its original position. The mathematical analogy is not, however, quite complete, whereas the hologram records the square of the Fourier transform of the wavefront leaving the object, the bank of resonators records the square of the Laplace transform of $f(t)$, because to record the Fourier transform would require a violation of causality.

This result can be generalized in two stages. First, it can be shown that if a signal $f(t)$ is arbitrarily partitioned into an earlier part f_1 and a later part f_2, then after the bank has "memorized" the whole signal, the input of f_1 will evoke a more or less distinct "echo" of g_2, immediately afterwards. The distinctness of the echo will be greater the more closely the temporal autocorrelation function of $f_1(t)$ approximates to a delta function at the origin.

Second, the bank may be used for memorizing, at widely different times, a number of different signals $f^{(n)}$, $n = 1, 2, 3, \ldots$ If these signals are so different that their mutual correlations can be neglected, then the later input of $f_1^{(m)}$ will evoke a more or less distinct echo of $g_2^{(m)}$ uncontaminated by any of the other signals that have also been recorded in the bank.

If the bank is used, in this way, for recording a number of different signals, there will obviously be a limit to the length of any one signal that can be recorded. This limit is, in fact, the reciprocal of the frequency spacing μ. But the bank can be made to regenerate signals of much greater length by connecting it to a regenerative feedback mechanism such that when the response g_n appears the signal f_n is fed back into the bank. Then, if the signals (f_1 then f_2), (f_2 then f_3), and so on, have all been recorded, the input of f_2 will cause the bank to re-create the long sequence (g_2 then g_3 then g_4 then g_5 and so on).

The resemblance of such behaviour to that of memory is sufficiently striking for one to wonder whether the brain may not employ systems of this general kind for recording temporal sequences such as those which are involved in speech and kinaesthetically controlled movement. If so, perhaps groups of cells could be detected which have the property of becoming more responsive to particular frequencies the more they are stimulated at those frequencies. Cells are already known which display an accurately sinusoidal metabolism, and have been tentatively identified as "biological clocks"[4]. Could such cells be vitally involved in the processes of temporal recall?

I thank Dr A. Moscowitz, Dr L. Harmon and Dr B. Julesz for helpful criticism, and the Bell Telephone Laboratories for their hospitality in the course of this work.

BOOK REVIEWS

SEALS

Seals of the World

By Gavin Maxwell, with John Stidworthy and David Williams (World Wildlife Series No 2) Pp xii+151+ 16 plates (London Constable and Co , Ltd , 1967) 45*s* net

Seals have been much before the public in England during the past few years owing to the conflict between the interests of fishermen, to whom they are pests, and of others to whom they are endearing creatures An attempt to reduce the numbers of the grey seal on some parts of our coasts has led to much ill-informed protest, but it is surely better that public opinion, however misguided, should be anxious that our fauna be preserved than indifferent to its destruction The publication of this book under the auspices of the World Wildlife Fund which is to receive "part of the proceeds" from its sale seems to be timed to take advantage of this feeling to whip up support for its propaganda

Seals have for thousands of years been of the greatest economic importance to the people who live near the shores of the northern oceans of the world, they yield food, oil, furs, hides, ivory and other useful products So long as seals were cropped for subsistence by people on the peasant level of life, all was well, but when, around the beginning of the nineteenth century, big business realized the wealth awaiting the gathering, an era of almost incredible destruction started Although seals are aquatic mammals they have not, as have the whales, completely emancipated themselves from the land, or ice-fields, to which they must resort to give birth to their young and nurse them through the first few weeks of life It is when they temporarily leave the sea and congregate in large herds that they are vulnerable to commerce

Local exploitation of seals, mainly for their oil, was carried out on a small scale in different parts of the world as European exploration advanced, but the devastation came at the turn of the eighteenth century when fortunes were made from fur seals, especially in the southern hemisphere, and in a couple of decades the animals were practically exterminated Throughout the nineteenth century the remnants were spasmodically hunted down, until early in the twentieth century even occasional raids no longer paid expenses It has taken half a century for the populations to begin showing signs of recovery Events in the north Pacific took a similar course, but were halted at a rather earlier time The sea lions and fur seals of South America, the elephant seals of the sub-Antarctic, and the fur seals of the north Pacific are now cropped rationally—an easy thing to do with polygamous species that have an excess of males The ice-field breeding seals of the north Atlantic, such as the harp, bearded and other seals, are, however, still over-fished although some measures for their conservation have been taken The history of sealing is disgraceful, but at the eleventh hour before the final disappearance of the animals reason is beginning to prevail, and the prospects of preserving the world populations of these scientifically fascinating animals, and of taking a crop of useful products from them for the benefit of mankind, seem to be brighter

Apart from their economic value seals are of the greatest interest to zoologists—their highly adapted anatomy, and the innumerable peculiarities of their physiology, have long attracted attention, and provide a host of problems for study by observation and experiment that will keep enthusiasts at work for many years The recently discovered use of sound echo-location in some species has opened yet another field of investigation—and now SCUBA divers are able to meet seals in their own element, even below the ice-fields of the Antarctic wastes

This book gives a short general account of seals, and of man's dealing with them, it then gives an account of each species in turn under headings such as distribution, appearance, habits, reproduction and so on It concludes with a list of the species and a short bibliography The author claims no originality in the work for which his two assistants ransacked the literature in search of material They have been industrious, and have collected most of the important facts about seals, and they have not copied over many of their predecessors' mistakes, though they have missed some of the latest discoveries There are a few misprints such as "deputations of sealing vessels" for "depredations" The interesting photographic illustrations show twenty-eight of the thirty-two species It is not clear, however, why this book should have been compiled, for a first-class book with the same title, written by Judith E King who has spent years in original research on seals, was published by the British Museum (Natural History) only three years ago at less than a quarter of the price of this volume L Harrison Matthews

ANOTHER JOURNAL

Biochemical Genetics

Vol 1, No 1, June 1967 Edited by Charles R Shaw Pp 1–71 Annual subscription (4 issues) $18 Outside US and Canada add $1 80 for postage and handling (New York Plenum Publishing Corporation, 1967)

Any new scientific journal is at present a mixed blessing library budgets are usually stretched to the limit, and the reading capacity of every research worker had already reached saturation some twenty years ago

In this light a new quarterly by the title *Biochemical Genetics* is unlikely to be welcome on the usual grounds of filling a non-existing gap

This said, what are the mitigating circumstances ? First, the proposed field of the journal states its primary interest in the biochemical genetics of diploid organisms Presumably this means organisms other than *Escherichia coli* and phage T_4 or, more generally, eukaryotes This is welcome, but it may lead to class consciousness and inferiority complexes Second, the editorial board includes a number of very distinguished people Third, the first number includes some good specialized papers To quote a few, one on polymorphism for alcohol dehydrogenases in maize, one on a new assay for galactose-urydyltransferase in cultured human cells, and one on ATP levels in erythrocytes of Negro and white Americans

Among the articles of general interest, there is one by Fitch and Margoliash on a method for estimating the number of invariant amino-acid coding positions in a gene

On the whole the first number is good, and if we have to be plagued by—and subscribe to—yet another journal, let us wish it as good a continuation G Pontecorvo

IN THE SUB-ANTARCTIC

Sub-Antarctic Sanctuary

Summertime on Macquarie Island By Mary E Gillham Pp 223+32 photographs (London Victor Gollancz, 1967.) 45*s*.

Macquarie Island is one of nine truly sub-Antarctic oceanic islands, scattered around the Southern Hemisphere between latitudes 50° and 60° south It is of volcanic origin, and was heavily glaciated at the height of the Quaternary ice ages Its meagre flora, vegetation of tussock grassland, damp moorland and feld-mark, sparse land fauna and enormous breeding colonies of sea birds and seals are typical of the oceanic sub-Antarctic. Soon after discovery, in 1810, the island's stock of fur seals was virtually exterminated by sealers and for a long period thereafter the elephant seals and penguins were exploited for oil. Sealers not only made great inroads into the native bird and mammal populations, but imported rabbits, cats and the New Zealand weka, and these species have had an equally devastating effect on the ecosystem The rabbits have undermined the vegetation on coastal slopes and caused widespread erosion, while cats and rats, jointly or separately, are thought to have exterminated the island's endemic flightless landrail and destroyed colonies of the smaller sea birds Altogether, Macquarie Island was in a sorry state in 1933, when it was declared a sanctuary for its surviving wild life even since then, its management has not been uniformly enlightened Sheep, pigs, chickens and goats have been deliberately imported by the Australian National Antarctic Research Expedition which has maintained a scientific station at Macquarie since 1948, and while the goats were later destroyed, the sheep (which appear to serve no useful purpose) continued, in 1960, when the author of this book visited the island, to damage the vegetation in the one area of the island not previously infested with rabbits.

The efforts of the Australian authorities to protect Macquarie have largely been successful in allowing the recovery of penguin, albatross and seal populations. there is little hope of restoration of the overall oceanic island ecosystem to the level to be seen in the less damaged sub-Antarctic islands of Iles Crozet, Prince Edward Island or the outliers of South Georgia At the same time, the island does provide, in its bird and mammal populations, an impressive wild life spectacle, it has given opportunities for some outstanding long-term research on penguin and elephant seal biology and population dynamics, and even if imperfect, it is the most effective sanctuary, so far established, in the sub-Antarctic zone

Dr Mary Gillham's book does not come up to the claims made for it on its dust cover It is not a "must" for the specialist because of the information it gives about current research programmes Most of the scientific detail within it will already be known to the specialist from other sources, and what is new is written in so anecdotal a style that its basis and authority cannot be checked The book, in fact, is a fluently written piece of popular natural history, resulting from a few weeks' visit in midsummer As would be expected from so experienced a plant ecologist, Dr Gillham's notes on plant distribution and succession—for example, in abandoned elephant seal wallow grounds or old penguin colonies—are penetrating and of real interest. Her account of zoological topics and of southern circumpolar ecology and biogeography as a whole is inevitably less first-hand and less authoritative, contains a sprinkling of minor errors and doubtful generalizations, and is occasionally spoiled by emotional anti-scavenger and anti-predator bias The book, taken by and large, is, however, an entertaining addition to the growing library of sub-Antarctic popular natural history It has good photographs, rather less satisfactory pen-and-ink drawings, a valuable bibliography, appendices and index, but is spoiled by the omission of an adequate map M W. HOLDGATE

REFLECTIVE ZOOLOGY

Invertebrate Structure and Function

By E J W Barrington Pp x+549 (London Thomas Nelson and Sons, Ltd , 1967) 60*s* net

THE study of the organization of the invertebrates has long formed a major constituent of many university courses in zoology The undergraduate frequently receives instruction on invertebrate structure and classification and also on comparative physiology, and has to knit this information together into a moderately coherent whole Professor Barrington's book attempts to bring about such a synthesis: it is intended, as he says, "that the book may serve as an accompaniment to the more general and reflective parts of a university zoology course; as a companion for the seminars, the tutorials and the essay writing"

The chapters are grouped together into six parts There is an introductory section on the general features of living systems, followed by five chapters on movement, six on aspects of metabolism, four on information and co-ordination, three on reproduction and life histories and finally three on intraspecific and interspecific relationships

The treatment of movement concentrates mainly on the anatomical organization of muscular systems, without much analysis of the means whereby propulsive forces are applied to the substratum or the medium. The hydrostatic skeleton is examined in a wide variety of different animals, but the role of geodesic connective tissue fibres in the body wall is not really made very clear The section on aspects of metabolism deals comprehensively and interestingly with feeding methods, but the treatment of respiration, excretion and osmoregulation is rather brief The chapter on sense organs contains some errors of detail no single vertebrate eye contains rhodopsin, iodopsin, porphyropsin and cyanopsin, the axons of crustacean stretch receptors are not myelinated (as indicated in Fig 14–1) and the caption to Fig. 14–5 is incorrect The two chapters on nervous systems are mainly concerned with the relation between structure and behaviour The author's explanations of how nervous systems work, in terms of the properties of their individual neurones, are vague and misleading; it is incorrect to suggest that, at the cellular level, inhibition is the opposite of facilitation The next chapter examines the organization of endocrine systems in some detail and provides a useful synthesis of structural and functional approaches The last six chapters deal with a variety of topics in reproduction, development and interrelationships between animals, in a way which is interesting and frequently illuminating, this part of the book is, I think, of a much higher standard than much of the preceding material The illustrations are numerous, clear and well set out. There is a selected bibliography at the end of the book.

Apart from these points of detail, however, there is a more fundamental criticism that can be made of this book. The subject matter is largely concerned with physiology and functional morphology; both of these are essentially experimental sciences, and the problems which occur in them are to be solved by experimental methods A study of these subjects should surely, therefore, include some treatment of what experiments have been done and how the evidence so acquired should be assessed It is not sufficient to feed a student of a scientific subject on a diet consisting almost entirely of hypotheses and conclusions: he must be brought into close contact with the imaginative processes involved in conceiving experiments and the rigorous processes of deduction required for their interpretation

If these criteria are to be applied, then Professor Barrington's book must be found wanting He presents the reader with a large number of conclusions, but only rarely does he give an adequate account of the evidence on which these conclusions are based Connected with this feature is a marked absence of the quantitative approach, both in the text and in his selection of illustrations, there are nearly three hundred diagrams, but only twelve of them are graphs or experimental records with quantitative axes For example, in the chapter on respiration we might reasonably expect to find, in a book of this nature, answers to some of the following questions What is the rate of oxygen uptake in any one particular animal? How can this be measured? What environmental factors affect it? Is oxygen uptake affected by the size of an animal? How much more oxygen is required by active animals? Do animals living in habitats with low oxygen concentrations show any anatomical adaptations for increasing their oxygen uptake? What does the dissociation curve of a respiratory pigment look like? None of these is dealt with Yet these are surely just the kinds of question that the attention of the student should be drawn towards, and especially so in his seminars, his tutorials and his essay writing D. J AIDLEY

BIRD'S EGG CHEMISTRY

Biochemistry of the Avian Embryo

A Quantitative Analysis of Prenatal Development By Alexis L Romanoff with the collaboration of Anastasia J Romanoff Pp xviii+398 (New York and London Interscience Publishers, a division of John Wiley and Sons, 1967) 156*s*

PROFESSOR ROMANOFF has long been an authority on the development of the avian embryo, and this, his latest production, is a valuable book which every embryologist, once he has seen it, will wish to have for frequent reference Compiled from an examination of more than 5,000 pertinent publications, the information is provided in an intelligible and palatable form, mostly by means of tables with adequate explanatory text and many figures Equally important are the large number of references and more than twenty pages of bibliography, where the reader may find more details and be able to investigate the biochemistry of his problem in depth Indeed, the book combines an introduction to chemical embryology and a reference manual for the advanced research worker in this field

It should be emphasized, however, that it is not a discourse on the biochemical processes occurring in the avian embryo, nor does it deal with the problem of differentiation and intercellular reactions On the contrary, it is more of an encyclopaedia of biochemical facts and figures relating to every component of intra- and extra-embryonic tissue or organ at frequent stages (usually every day) from the beginning of incubation to hatching Even those who have ceased to marvel at the transformation of the contents of a bird's egg into an independent viable organism will learn a great deal to their advantage and be grateful to the authors for the labour of collecting so much and presenting it in so little space.

It is with my tongue in my cheek that I direct attention to page 122 where the total blood volume within the chick egg on the eighteenth day is reported as reaching its peak of 2,900 ml Reference to the accompanying tables soon reveals that 2,900 mm³ is the intention—a more acceptable figure JOHN MCKENZIE

THYMIDINE IN CELLS

Thymidine Metabolism and Cell Kinetics

By J E Cleaver (North-Holland Research Monographs Frontiers of Biology Vol 6) Pp 259 (Amsterdam North-Holland Publishing Company, 1967) 86*s*.

THE introduction of the radioactive isotopes of carbon, phosphorus, sulphur and hydrogen into the biological sciences during the past two decades has permitted great advances in our understanding of the structure and function of living matter A significant factor in their use is that they can be incorporated by living tissues without giving rise to excessive disruption of metabolic processes by virtue of their radioactivity

Cleaver's monograph deals specifically with work done using tritium (H_3) labelled thymidine, a unique compound that is almost exclusively incorporated into cell DNA and therefore makes possible very specific marking of this important macromolecule Possible uses which come to mind are studies of DNA replication, chromosome and nuclear distribution, the cell cycle and population kinetics Early chapters in the book discuss methods of preparation and detection of the compound, as well as what is known about thymidine metabolism in various types of cell Experimental details are generally not included (they would, in any case, make the book unnecessarily complicated), but this is compensated for by a comprehensive bibliography The use of tritiated thymidine in following events during the cell cycle occupies the larger part of the book, including a treatise on the kinetics of defined cell populations The text is well supplemented with simplified diagrams, and those less mathematically minded are spared the complicated theory and assumptions involved in the use of radioactive thymidine until a final appendix.

Dr Cleaver is mainly concerned with mammalian cells, but does not ignore the results obtained from micro-organisms, plants and insects Such cell types especially have contributed to our knowledge of chromosome replication, the segregation patterns of chromatids after mitosis, and of cross-overs during meiosis In treating the cell cycle, the various phases of which are usually represented schematically by sectors on a clock face, the mammalian cell is used almost exclusively as a model A large number of different cell types have now been characterized with respect to the duration of each part of the cycle, both *in vitro* and *in vivo*, and it is of interest that the G_1 phase (between mitosis and DNA synthesis) has greater variability between different cell types than either the DNA replication phase (S) or the period following replication (G_2) The commonly held fallacy that tumour cells have a higher growth rate than non-malignant cells was exposed as such by comparing the respective cell cycles

In writing the book, Dr Cleaver has assumed the reader to have a certain fundamental knowledge of the Watson and Crick hypothesis, the mitotic cycle, and of the basic organization of cell nuclei. The application of tritiated thymidine to such problems, however, is fully discussed Though our understanding of chromosome structure and its mode of replication in diploid cells is less precisely known than in haploid unicellular organisms, models based on the latter are suggested for the more advanced cell types

The index might usefully have included those authors mentioned in the text It may also be that the immunologist will be a little hurt that the interesting mitotic events following antigenic challenge have been largely ignored These, however, are minor criticisms, and research workers in any way involved in the study of nuclear DNA are likely to find the monograph of invaluable assistance and a useful reference source

A. J. S. DAVIES

NON ANGELI SED AVES

Radar Ornithology

By Eric Eastwood Pp. xii+278+24 plates (London: Methuen and Co, Ltd, 1967) 75*s*. net.

To speak of a new science, as does the author, is surely an enthusiastic exaggeration A new technique has certainly been exploited in the past dozen years by those ornithologists who parasitically battened on to early-warning or airport radars It now has such an accepted place in bird migration studies that it is hard to appreciate the difficulties early users had in convincing radar technicians that many anomalous echoes on their screens, classified by some anonymous wit as "angels", really did have wings

Future practitioners may appreciate this book, with its reasonably clear enunciation of radar principles and practice and its summary of the few score of original papers that have appeared to date Until recently one might have wondered whether there would be many such people High power, long-range radar equipment is far too expensive for ornithologists and the showers of angels were an obscuring nuisance to the prime users of the sets Technical advances could soon have resulted in their elimination Modern aircraft, however, are showing an increased tendency to collide with birds, so a new and economically important interest has arisen as to where birds are flying A radar watch for migratory concentrations may therefore become a standard requirement for airport controllers But the majority of airstrikes are on military aircraft streaking along below radar cover, or on take-off and landing, so one should not, perhaps, have too high hopes that ornithologists of the future will have access to a regular mine of photographic records of migrations in progress

They will have to be dedicated men While the speeded up cine film of a radar display is alive and exciting, the individual frames are deadly dull, as witness the many plates adding substantially to the high cost of this book To the uninitiated they are just one lot of "damned dots" after another Nor are the attempts to represent them in diagrammatic form much happier Dozens of little maps sprinkled with tiny arrows give more the impression that hostilities have broken out in the Channel and that Harold is again in danger of personal disaster To be fair, radar studies of migration are not alone in having failed to achieve an attractive form of presentation The compilations of visual records from bird observatories, plastered with endless synoptic charts, have set a high standard of boredom Indeed, this may be the reason for one of the main lacks in this book, there is no thorough-going attempt to relate radar findings (many of which are not novel) with the information obtained by other methods of studying migration

Perhaps more emphasis should have been laid on the crucial weaknesses of the radar method, the inability to describe, other than in very broad categories, the numbers or the kinds of birds involved in the choirs of "angels" It is said that specific identification of the "signatures" of radar echoes may be possible for single birds at short distances Sadly, those seeking to follow up the reference to the (10 cm) radar detection of pulsations in the pectoral muscles of a small passerine will not find it published in the *Proceedings of the International Ornithological Congress* as specified (or anywhere else for that matter) The reference list also omits a number of relevant publications in ornithological journals, but does usefully give some papers in technological offerings that would not normally come the way of the ornithologist

The book is well produced and free from typographical mistakes G V T MATTHEWS

WAVEGUIDES IN THEORY

The Theory of Waveguides and Cavities

By R A Waldron Pp xiii + 120 (London Maclaren and Sons, Ltd , 1967) 32*s* net

Theory of Waveguides and Cavity Resonators

By Emile Argence and Théo Kahan Pp xv + 424 (London and Glasgow Blackie and Son, Ltd , 1967) 120*s* net

ALTHOUGH the two books which form the subject of this review bear almost the same title, this is practically the only common factor between them The first text, by Richard Waldron, has as its core a number of papers published by the author in 1961 It is essentially intended for research workers studying waveguide boundary value problems or the theory underlying the measurement of dielectric or ferrite properties using cavity resonators

In the introductory chapter the concept of the HSP (homogeneous–simple–perfect) waveguide is presented and its properties are reviewed Later the author proposes that a 1 1 correspondence exists between modes in non-HSP and HSP guides Although no general proof is given the proposition does appear to be borne out by experience In Chapter 3 the author argues strongly that in approaching a new non-HSP waveguide problem one should seek to identify modes with those of the HSP guide The fourth chapter sets out the author's views on mode nomenclature with illustrations drawn from the behaviour of circular waveguide containing an axial dielectric rod Chapter 5 attacks the concept of surface impedance when used in the determination of the complex propagation coefficient of a mode in a waveguide with imperfectly conducting walls Undoubtedly Waldron's point is valid, but it would be instructive to have a comparison made with an exact rather than perturbation solution of the non-HSP waveguide problem With present day computers this is quite feasible, and could form a valuable study Chapter 6 presents a critical derivation of the formula for the determination of the complex permittivity and permeability of a small sample introduced into a resonant cavity The next chapter extends perturbation theory to include waveguides After a derivation of the static expressions for fields in small ellipsoids, the final chapter makes a careful appraisal of cavity methods of measuring ferrite properties

Although Waldron's style of writing will not appeal to all, there is something to be said for "black and white" statements in a monograph of this kind Undoubtedly some readers will be stimulated to make their own examination of the problems described

The second book, a translation from the French, was specially prepared for science faculty students obliged to study on their own So far as British students are concerned, however, the treatment is such as to appeal principally to those graduates in mathematics or theoretical physics who have an interest in electromagnetic problems There is a nine chapter mathematical introduction which, in part, aids understanding of the sixteen chapters dealing with electromagnetic fields, waveguides and cavities which follow The introduction includes three quite substantial chapters on the theory of distribution which I did not find to be essential to my understanding of the main work of the book The section on the electromagnetic field contains an account of Mie's analysis of diffraction by a dielectric sphere and the integral equation method of Levine and Schoninger, applied to the same problem The section on waveguides commences with a treatment of plane wave propagation in a dispersive absorbing medium, which is followed by a review of basic circuit theory A general theory of propagation in waveguides is then considered and results for specific waveguides follow. If thus far a certain incoherence in treatment seems apparent, this impression is probably justified From the remaining chapters those describing the modal analysis of source excited waveguides, due to Felsen and Mascuritry, and the application of radiational methods are noteworthy The whole book really comprises a selection of topics in electromagnetic theory intended for the advanced student The treatment is essentially mathematical with rather sparse physical descriptions, however, the originality of approach may appeal to those having reasonable familiarity with the subject matter In places the presentation of important subjects is terse, whereas elsewhere a student with mathematical competence could easily follow the steps

P J B CLARRICOATS

TODAY'S RADIO TELESCOPES

Radioastronomical Methods of Antenna Measurements
By A D Kuz'min and A E Salomonovich Translated by K N Tirogoff Translation edited by Ernest Jacobs (Electrical Science a Series of Monographs and Texts) Pp xvi+182 (New York Academic Press, Inc , London Academic Press, Inc (London), Ltd , 1966) $8 50

THE past ten years have witnessed an impressive growth of new telescopes which can explore the Universe by radio and radar One of the earliest of this generation of radio telescopes, the 250 ft diameter Mark I at Jodrell Bank, has now completed ten years of service in planetary, galactic and extragalactic studies It has since been joined by an international group of large fully or partially steerable telescopes including the 210 ft at Parkes, Australia, the 300 ft at Greenbank, USA, the 1,000 ft in Aricebo, Puerto Rico, and the 660 ft × 130 ft tiltable plane mirror at Nançay, France A new generation of telescopes capable of operating at very short wavelengths (2 cm or even shorter) has been put into service during the past two years Three such instruments 140–150 ft in diameter have been installed in eastern USA and Canada and already have been able to satisfy an upsurge of interest in the short wavelength emission from quasars and other compact radio galaxies and in the structure of galactic ionized hydrogen regions seen both in their continuum emission and in their recombination line emission Other large telescopes have been built by Russia and USA for tracking deep-space probes

Unfilled aperture telescopes with large spacings of their component collecting areas, and consequently higher resolution than the filled aperture telescopes, have also been developed during this period These include the 1 mile synthesis telescope at Cambridge, the 1 mile cross telescope at Molongo, Australia, and the 1 9 mile diameter ring telescope at Culgoora, Australia

Radio astronomy is an integral part of the broad front of astronomy and has provided a strong impetus to many branches of the subject, particularly galactic structure and topics relating to cosmology The quest for more sensitive and versatile telescopes to pursue these studies continues The Dutch are well on the way towards completing an ambitious synthesis system at Westerbork, while the German radio astronomers are preparing to build a 330 ft fully steerable telescope near Bonn with a grant from the Volkswagen Foundation In Great Britain a move has been made towards the construction of a 400 ft telescope to operate at wavelengths down to 20 cm or shorter when the Science Research Council decided to negotiate a contract for a final design study American radio astronomers have been given support by the Dicke committee of the National Science Foundation in their request for a large synthesis system consisting of eight 130 ft telescopes and for the resurfacing of the 1,000 ft Aricebo telescope to enable it to work down to 10 cm wavelengths

An important part of the commissioning procedure for any new telescope is the accurate calibration of the position of its electrical axis and of the telescope gain at various wavelengths The book *Radioastronomical Methods of Antenna Measurements* by A D Kuz'min and A E Salomonovich provides the background for such measurements These two radio astronomers from the Lebedev Physical Institute, Moscow, have first hand experience in this field with their 72 ft telescope which has a good performance at wavelengths down to 8 mm They discuss in detail the basic concepts of receiver design and calibration in addition to those of aerial gain measurement Their treatment, which is rigorous throughout, also includes an estimate of the effects of atmospheric refraction and absorption, the effects of finite time constant and beam width on the measurement of radio sources

A useful parameter in evaluating the performance of the combined aerial and receiver system when used to detect weak signals as in radio astronomy or communications operations is the ratio of aerial gain to system noise figure This concept, which is hinted at in the book, underlines the compromise which has to be struck between highest aerial gain of a given reflector and the consequent contribution to system noise by the aerial spillover With the advent of high performance low noise receivers operating at a few tens of degrees Kelvin input noise temperatures, this parameter is a fundamental factor in aerial design

This book has concentrated entirely on the calibration of filled aperture radio telescopes and has shown how radio sources can be used for this purpose There are related problems in setting up and calibrating non-filled aperture telescopes These instruments provide the ultimate in accurate angular location Now that very long baseline interferometers have been successfully established the process can be inverted to derive the interferometer baseline to a fraction of a wavelength from astronomical observations These measurements could be of geophysical importance

The translators have performed a valuable service in making this excellent book available in the English language They have included many explanatory footnotes to the text There are, however, traces of literal translation in some passages as well as many typographical errors in the text, including a misleading factor of 10^2 in Table 4 which gives the flux density of radio sources suggested for calibration purposes These are not major blemishes in a book which will be found useful to those working in radio astronomy and in communications systems R D DAVIES

ENGLISH FOR GERMANS

Dictionary of Science and Technology, English–German
Compiled and arranged by A F Dorian With the co-operation of L Herzbruch Pp 1,238 (Amsterdam, London and New York Elsevier Publishing Company, 1967) 180*s*

THIS English–German dictionary which, so the blurb says, includes reference to the most important terms from 128 different fields of science and technology, should be very useful to anyone having to translate technical English into German The German scientist reading a vitally important English paper, if he does not speak English already, which he probably does, should be pleased to have recourse to this single volume covering all branches of physical and biological science So should the translator busy rendering complex scientific English prose into German, or anyone else who needs to know the German equivalent of the many words which fill the seven centimetres between the covers of this book

Each word has an explanation of the branch of science from which it comes, together with its translation, for example tranquillizer [med] Beruhigungsmittel *n*, rudderhole [naut] Ruderstockoffnung *f*, hidradenitis [med] Schweissdrusenentzundung *f* There are also often explanations of the meaning of the words, for example mind [gen] (abstract term for any form of collective intelligence) Sinn *m*, Gemut *n*, hexachloroethane [chem] (a rubber accelerator and camphor substitute in celluloid manufacture) Hexachlorathan *n*, Perchlorathan *n* These explanations might be of more use to readers if they were in German, after all, the English translator is more likely to know what the English words mean than is the German scientist to be able to understand the explanation

Revised and enlarged editions of the dictionary are to follow every eight years to keep the work up to date, and the German–English volume will appear this year to complete a useful set MARY LINDLEY

University News :

Birmingham

Dr T P Whitehead has been appointed professor of clinical chemistry (part-time).

Glasgow

Mr W Bryan Jennett, a consultant neurosurgeon with the Institute of Neurological Science, has been appointed to the new chair of neurosurgery.

London

Professor K W Keohane, professor of physics at Chelsea College of Science and Technology and co-ordinator of the Nuffield Foundation Science Teaching Project, has been appointed to the chair of science education tenable at that college The title of professor of animal behaviour has been conferred on Dr J S Kennedy, in respect of his post at the Imperial College of Science and Technology

Reading

Dr G. W. Series, at present university lecturer in the University of Oxford, has been appointed to a chair of physics

Strathclyde

Dr Edward Eisner, of the Mechanical Research Department of Bell Telephone Laboratories Inc , New Jersey, has been appointed to the new chair of applied physics

Appointments

Dr L C F. Blackman has been appointed director-general of the British Coal Utilization Research Association

Mr J N R Jeffers, at present head of the Statistics Section of the Forestry Commission, has been appointed director of the Nature Conservancy's Merlewood Research Station at Grange-over-Sands, Lancashire

Mr Donald F Moore, formerly deputy federal co-ordinator for meteorological services and supporting research, has been appointed assistant administrator for plans and programmes of the Environmental Science Services Administration, US Department of Commerce

Meetings

Protein Structure and Function, January 22–23, University of Miami (Dr E L Chambers, University of Miami School of Medicine, P O Box 875, Biscayne Annex, Miami, Florida 33152).

Power Group Winter Meeting of the Institute of Electrical and Electronics Engineers, January 28–February 2, New York (Institute of Electrical and Electronics Engineers, 345 East 47th Street, New York, NY 10017)

Rheumatism, February 17–21, Bombay (Dr M M Desai, c/o Indian Rheumatism Association, Fateh Manzil, 457–459 Lamington Road, Bombay 4)

Fundamental Cancer Research, March 6–8, Houston (Dr Manley Mandel, Chief, Section of Molecular Biology, Department of Biology, M D. Anderson Hospital and Tumor Institute, University of Texas, Houston, Texas 77025)

Modern Chemistry in Industry, March 11–14, Eastbourne (Society of Chemical Industry, 14 Belgrave Square, London, SW1)

New Approach to Machine Tools in Relation to the Components They Make, March 20, Institution of Mechanical Engineers (R S Glynn, Head of the Conference Department, The Institution of Mechanical Engineers, 1 Birdcage Walk, Westminster, London, SW1)

Thermodynamics and Fluid Mechanics, March 27–29 University of Bristol (Groups Department, The Institution of Mechanical Engineers, 1 Birdcage Walk, Westminster, London, SW1)

Heat Transfer and Fluid Dynamics of Near Critica Fluids, March 27–29, Bristol (The Institution of Mechanical Engineers, 1 Birdcage Walk, Westminster, London SW1)

Surface Chemistry of Oxides, March 28–29, University of Nottingham (Dr G C Parfitt, Department of Chemistry University of Nottingham, Nottingham)

Thermophysical Properties, April 1–4, University of Maryland (Mr J R Moszynski, Symposium Chairman Department of Mechanical and Aerospace Engineering University of Delaware, Newark, Delaware 19711).

Cell Biology, April 4–5, Middlesex Hospital, London (Dr L M Franks, Secretary-Treasurer, British Society for Cell Biology, Imperial Cancer Research Fund, Lincoln's Inn Fields, London, WC1)

Thermodynamics, April 8–10, Manchester (Dr H A Skinner, chairman, c/o University of Manchester, Oxford Road, Manchester 13)

Vacuum Congress, April 17–19, Reynold Building of the University of Manchester Institute of Science and Technology (Mr J Yarwood, Technical Secretary of the Congress, 47 Belgrave Square, London, SW1).

Genetics and Breeding of *Streptomyces*, May 31–June 2, Dubrovnik (Dr M Alačević, Secretary, Symposium on Genetics and Breeding of *Streptomyces*, Faculty of Technology, University of Zagreb, Zagreb, Pierottijeva 6/IV, Yugoslavia)

Photosynthesis Research, June 4–8, Freudenstadt (Black Forest) (Professor H Metzner, International Congress of Photosynthesis Research, c/o Institut fur Chemische Pflanzenphysiologie der Universität-Tubingen, 72 Tubingen, Germany)

Vacuum Microbalance Techniques, June 17–18, Technological University of Eindhoven (Pat Gaskins, Secretary, Seventh Conference on Vacuum Microbalance Techniques, 7500 Jefferson Street, Paramount, California 90723)

Precision Electromagnetic Measurements, June 25–28, Boulder Laboratories of the National Bureau of Standards (George Goulette, Bureau of Continuation Education, 328 University Memorial Center, University of Colorado, Boulder, Colorado 80302)

Erratum. In the communication "Taylor Vortices with Eccentric Rotating Cylinders" by J A Cole (*Nature*, 216, 1200, 1967) the reference mentioned in the first and eighth lines of the third paragraph and in the second line of the last paragraph should be No 3 and not No 2

Erratum. In the article "Site of Attachment of Retinal in Rhodopsin" by Deric Bownds (*Nature*, 216, 1178, 1967) the last sentence of the fifth paragraph should read "They contain rhodopsin in a large micelle with digitonin". In the seventh line of the seventh paragraph 100° should read 110°

Erratum In the communication "Density Distribution Analysis of Lymphocyte Populations' by Ken Shortman *et al* (*Nature*, 216, 1227, 1967) the first lines of the legends of Figs 4 and 5 should refer to cells which form haemolytic antibody and not haemolytic cells which form antibody In the following communication "Density Distribution Analysis of Antigen Sensitive Cells in the Rat" by J S Haskill (*Nature*, 216, 1229, 1967) the references should be altered so that the first paragraph ends "The technique is that of sedimentation to equilibrium in density gradients of bovine serum albumin[7,8]" In the rest of the communication references mentioned in the text should read 9 for 8, 10 for 9 and 11 for 10.

FORTHCOMING EVENTS

(Meetings marked with an asterisk are open to the public)

Monday, January 8

Institution of Electrical Engineers (at Savoy Place London, WC2), 5 30 p m—Discussion Meeting on "Domain Originated Functional itegrated Circuits 'DOFICS' ", opened by Mr C P Sandbank

Institution of Electrical Engineers (at Savoy Place, London, WC2), 5 30 p m—Discussion Meeting on "Logarithmically Periodic Aerials", pened by Mr M F Radford

Society of Chemical Industry, London Section (joint meeting with ie Colloid and Surface Chemistry Group, at 14 Belgrave Square, London, W1), at 5 30 p m—Mr H W Vallender "Whither Detergents"

Monday, January 8—Tuesday, January 9

Society of Chemical Industry, Pesticides Group, and the Phyto-hemical Society (at the School of Pharmacy, Brunswick Square, London, VC1)—Symposium on "Plant Growth Regulators"

Tuesday, January 9

Chemical Society, Nucleotide Group (in the Chemistry Department, Jniversity of Birmingham), at 10 30 a m—Inaugural Meeting

Institution of Electrical Engineers (at Savoy Place, London, WC2), t 5 30 p m—Discussion Meeting on "Electrical Signals for Data Acquisition nd Transmission—What Form Should They Take?", opened by Mr R E ischbacher

Institution of Mechanical Engineers, Automobile Division and Ianipulative and Mechanical Handling Machinery Group (at 1 Bird-age Walk, Westminster, London, SW1) at 6 p m—Mr H C Cox and Mr E Norman "The Design of Automobile Door Latches"

Institution of the Rubber Industry, London Section (at the Eccleston Hotel, Victoria, London, SW1), at 7 p m—Mr G Lambsdale "Overcoming Communication Problems in Process Industries"

Tuesday, January 9—Thursday, January 11

Chemical Society (in the Physical Chemical Laboratory, South Parks Road, University of Oxford), at 9 a m daily—International Symposium on "Valence and Reactivity"

Wednesday, January 10

Mineralogical Society (in the Department of Geology and Mineralogy, The University, Parks Road, Oxford)—Meeting on "Choice of Methods in Geochemical Analysis"

Institute of Fuel, and the Institute of Marine Engineers (at 76 Mark Lane, London EC3)—Symposium on "Combustion in Marine Boilers" *

Geological Society of London (at Burlington House, Piccadilly, London, W1), at 5 p m—Mr J G Jones "Intraglacial Volcanoes of the Laugarvatn Region, South-West Iceland", Dr R C Selley "Near-Shore Marine and Continental Sediments of the Sirte Basin, Libya"

Institution of Electronic and Radio Engineers (at 8–9 Bedford Square, London, WC1), at 6 p m—Professor J Merhaut "Some Aspects of Electrostatic Loudspeakers"

Institution of Mechanical Engineers Applied Mechanics Group (at 1 Birdcage Walk, Westminster, London, SW1), at 6 p m—Discussion Meeting on "Current Problems in the Pressure Vessel Field"

Institute of Information Scientists (at Knightway House, 20 Soho square, London W1), at 6 15 p m—Dr A J Barrett "The Engineering Sciences Data Service"

Thursday, January 11

Institution of Electrical Engineers (at Savoy Place, London WC2), at 5 30 p m—Discussion Meeting on "Electrical Properties of Polyolefines", opened by Mr W Reddish

Institute of Petroleum (at 61 New Cavendish Street, London, W1), at 5 30 p m—Mr R G Henbest "Gas Turbines for Peak Load Generation"

Institution of Mechanical Engineers, Thermodynamics and Fluid Mechanics Group (at 1 Birdcage Walk Westminster, London, SW1), at 6 p m—Discussion Meeting on "Fuel Cells"

Friday, January 12

Chemical Society Protein Group (at the Geological Society, Burlington House, Piccadilly, London, W1), at 2 p m—Inaugural Meeting

Saturday, January 13

Bone and Tooth Society (at the Zoological Society, Regent's Park, London, NW1), at 10 a m—Meeting on "Comparative Bone Disease"

Monday, January 15

Institution of Electrical Engineers (at Savoy Place, London, WC2), at 5 30 p m—Discussion Meeting on "Project Problems" opened by Mr A Draper

APPOINTMENTS VACANT

Applications are invited for the following appointments on or before the dates mentioned

Senior Lecturer in Ophthalmology—The Registrar, The University of Manchester, Manchester, 13 quoting Ref 192/67 (January 10)

Digital Computer Programmer (with previous programming experience and preferably mathematics to degree level)—The Principal, Lanchester College of Technology, Priory Street, Coventry (January 11)

Lecturer or Assistant Lecturer (preferably with research interests in some branch of operational research or computational statistics) in the Electronic Computing Laboratory—The Registrar and Secretary, The University Leeds, 2 quoting Ref 68/21/1 (January 12)

Head of the Department of Mathematics—Clerk to the Governing Body, Woolwich Polytechnic, Wellington Street, London, SE18 (January 19)

Senior Experimental Officer (with a degree or equivalent qualifications) in the Palaeoecology Laboratory, for duties which will include responsibility for the operation, maintenance and development of radiocarbon dating equipment—The Secretary to the Academic Council, The Queen's University, Belfast, Northern Ireland (January 20)

Lecturers or Assistant Lecturers in Biochemistry, Genetics, Plant Physiology, and Animal Behaviour—The Assistant Registrar (Establishment), The University of Sussex, Essex House, Falmer, Brighton, Bn1 9QQ, quoting Ref 856/5 (January 21)

Lecturer/Senior Lecturer (with an appropriate degree, training and experience in pasture agronomy, and preferably experience with tropical species) in Agriculture at the University of Queensland, Australia—The Association of Commonwealth Universities (Branch Office) Marlborough House Pall Mall, London SW1 (London and Brisbane January 26)

Senior Lecturer/Lecturer in Organic Chemistry at the Australian National University—The Association of Commonwealth Universities (Branch Office), Marlborough House, Pall Mall, London, SW1 (Australia and London January 30)

Assistant Lecturer/Lecturer (preferably with experience in enzymology and willing to develop investigations into the enzymology of lipids) in the Department of Biochemistry—The Registrar, The University, Liverpool quoting Ref RV/301 (January 31)

Lecturer in Civil Engineering (mainly for administrative duties) at the University of Sydney, Australia—The Association of Commonwealth Universities (Branch Office), Marlborough House, Pall Mall, London, SW1 (Australia and London, January 31)

Lecturer in the Department of Experimental Pathology, Faculty of Medicine and Dentistry, University of Birmingham—The Assistant Registrar, Medical School, Birmingham, 14 (January 31)

Lecturer (with previous research and/or teaching experience in the field of physical chemistry and a Ph D or equivalent qualifications) in Physical Chemistry at the University of New South Wales, Australia—The Association of Commonwealth Universities (Branch Office), Marlborough House, Pall Mall London, SW1 (Australia and London January 31)

Research Fellow in Neurochemistry (Biochemistry) at the John Curtin School of Medical Research, Australian National University—The Association of Commonwealth Universities (Branch Office), Marlborough House, Pall Mall London, SW1 (Australia and London, January 31)

Chair of Chemical Pathology at St Bartholomew's Hospital Medical College—The Academic Registrar (A), University of London, Senate House, London, WC1 (February 2)

Senior Lecturer or Lecturer in the Department of Zoology, University of Khartoum—The Secretary, The Inter-University Council for Higher Education Overseas, 33 Bedford Place, London, WC1 (February 13)

Senior Lecturers or Lecturers (2) in (*a*) Modern Algebra, (*b*) Topology, or (*c*) Functional Analysis at the University of Khartoum—The Secretary, Inter-University Council for Higher Education Overseas, 33 Bedford Place, London, WC1 (February 13)

Chair of Philosophy at the University of Tasmania—The Association of Commonwealth Universities (Branch Office) Marlborough House, Pall Mall, London, SW1 (Australia and London, February 19)

Lecturer (experimental or theoretical physicist with experience in nuclear structure research) in Nuclear Physics—The Registrar, King's College (University of London), Strand, London, WC2 (February 28)

Assistant or Associate Professor in Mammalogy—Professor H E. Welch, Head of Zoology, University of Manitoba, Winnipeg, Canada

Assistant Professor or Associate Professor to assume responsibility for the development and operation of undergraduate laboratories and lecture demonstrations—The Chairman, Physics Department, University of Alberta, Edmonton, Alberta Canada

Biochemist, Basic Grade (with an honours degree in chemistry or biochemistry or equivalent qualifications)—The Group Secretary, Wolverhampton Hospital Management Committee, Royal Hospital, Wolverhampton

Graduate Research Assistant (preferably with previous experience in the field of tissue culture) to work in an organ culture laboratory—The Secretary, St Mary's Hospital Medical School Paddington London W2

Lecturers and Assistant Lecturers in Mechanical Engineering—The Registrar The University of Manchester, Manchester, 13

Research Assistant for work on cell culture using foetal and adult haemopoietic tissue—Dr G D Pegrum, Department of Haematology, Charing Cross Hospital Medical School, 62–65 Chandos Place, London, WC2

Research Assistant in the Department of Medicine for work involving the investigation of metabolism of collagen in bone disease—Professor J. Anderson, Department of Medicine, King's College Hospital, Denmark Hill, London, SE5

HOW TO BUY NATURE

Volumes start in January, April, July and October, but subscriptions may begin with any issue

The direct postal price per subscription for one or two copies of NATURE each week is

***12 MONTHS** (52 issues and 4 indexes)

Great Britain and Eire		**£14 0.0** each
United States of America	(by air freight)	**$48** each
Canada	(by air freight)	**$52** each
Elsewhere overseas by surface mail		**£14 0 0** each

(Charge for delivery by air mail on application)

*Shorter periods *pro rata* (Minimum three months)

MULTIPLE SUBSCRIPTIONS

For subscribers who take more than two copies of NATURE each week these reduced annual rates are offered

12 MONTHS (52 issues and 4 indexes)

Number of Copies	*G B & Eire*	*U S.A*	*Canada*	*Elsewhere (surface mail)*
		(by air freight)		
	Each	*Each*	*Each*	*Each*
3–5	**£13 10 0**	**$46 50**	**$50 50**	**£13 10 0**
6–11	**£12 15 0**	**$44 50**	**$48 30**	**£12 15 0**
12 or more	**£12.0 0**	**$42.50**	**$46 00**	**£12 0 0**

Multiple subscriptions must run concurrently Every copy will be posted separately, and for speed of delivery each subscription can be addressed to a different individual or department at the same address (ZIP essential for U S A.)

Biologists know

EDWARD GURR LTD.

East Sheen, London, SW14

specialize in the production of

'MICHROME'

Stains & Reagents for Biology

and that the trade mark **"Michrome"** is synonymous with **Quality, Reliability, Prompt delivery** and **Technical Information Service**

Chemists and Physicists know

as do other scientists and technologists concerned with

Industrial Research and Production

that **EDWARD GURR LTD.** are very useful people to know when problems arise which could be overcome by the use of suitable dyes

The number of different synthetic dyes available at the present time is enormous Each dye has its own individual physical and chemical characteristics It is our business to know which particular dye is likely to serve best, as a research or production tool, for a particular project

We invite enquiries for:

DYES FOR USE IN ALL INDUSTRIES

(except the Textile Industry)

and hold stocks of a great variety of dyes, ready for immediate despatch to such industries as

AGRICULTURE, AIRCRAFT, ANODIZING, BUILDING, CONCRETE CHEMICALS, DRUGS, DIAGNOSTICS & PHARMACEUTICALS, ENGINEERING, ELECTROPLATING, HORTICULTURE, INKS, METALS, MOTOR & CYCLE ACCESSORIES, PETROL, OIL & WAXES, OPTICAL, PAPER PESTICIDES, COLOUR PHOTOGRAPHY, EMBALMING, OFFICE SUPPLIES, PUBLIC HEALTH, RADIO & TELEVISION, SHIPPING, VARNISHES, TIMBER & FORESTRY, etc

Among the dyes held in stock are

Amaranth, BPC, Cyanine, Dicyanine, Fast Bordeaux O, Aurantia, Fluorescein potassium, Crystal violet, BPC, Scarlet R, BPC, Diazonium salts, Neutral violet, Lacmoid, Nile blue, Janus green, Brilliant green BPC, Rosolic acid, Indophenol, Phloxine, Methyl green, Magneson, p-Ethoxychrysoidin, Pyoktannin, Pinacryptol yellow, Methyl red, Methyl orange, Uranine, Nitrazine yellow, Pinacryptol green, etc

■ ■ ■ ■ ■ ■ ■ ■ ■ ■ ■ ■ ■ ■

Biologists are invited to send for our latest catalogue of

'MICHROME' Stains & Reagents for Biology

which lists over 3,000 currently available items including

Acridine orange, Amido black 10B, Aquamount, Euchrysins, Fluormount, Fluoroil, Laktoseal, Lipid crimson, Luxol fast blue, LVN, Celloidin, Matamount, May-Grunwald, Jenner, Leishman, Giemsa, Toluidine blue, Cresyl fast violet, p-Xylenol blue, Trifalgic acid*, Rhodanile blue*, Chromosome red (Haplo)*, Nuclear fast reds, Papanicolaou stains, Shorr, Wright stain, Sienna orange, Thioflavine S, Thioflavine T, Brilliant cresyl blue Nile blue Uvak, Pyronin Y, Falg stain (for detecting protein-calorie deficiency and state of health in man and animals)*, etc

* Information leaflets available (gratis) on request

APPOINTMENTS VACANT

UNIVERSITY OF LANCASTER

DEPARTMENT OF MATHEMATICS

Applications are invited for several posts at the grade of Lecturer or Assistant Lecturer in the fields of

APPROXIMATION THEORY, NUMERICAL ANALYSIS COMPUTER SCIENCE

The undergraduate mathematics degree course has a substantial content of abstract mathematics as well as stochastic mathematics and its applications together with the topics mentioned above The Department is also responsible for a newly established first degree course in computer science Neighbouring Departments of Systems Engineering Operational Research, Economics and Financial Control provide a stimulating environment

Further particulars may be obtained (quoting Ref L 269/D) from the University Secretary, University House Bailrigg Lancaster, to whom applications (four copies) should be sent not later than January 31, 1968 (48)

UNIVERSITY OF LANCASTER

ASSISTANT LECTURER/ LECTURER IN ELECTRONICS

Applications are invited for appointment from October, 1968, to this new post in the Department of Physics Candidates should have postgraduate experience in the theory and use of microwaves or solid-state microwaves devices Salary scale £1,105 to £1,340 per annum (Assistant Lecturer) or from £1,470 (Lecturer) plus F S S U benefits

Further particulars may be obtained (quoting Ref L 270/C), from the University Secretary, University House, Bailrigg, Lancaster, to whom applications (one copy) naming two referees should be sent not later than February 16, 1968 (46)

CHEMIST WITH AN INTEREST IN GAS chromatography required to join team working on metabolic disorders in children Salary on scale £930 to £1 733 per annum according to experience—Applications with names of two referees to Chemical Pathologist Hospital for Sick Children, Great Ormond Street, W C 1 Enquiries welcomed (52)

UNIVERSITY OF LONDON KING'S COLLEGE

Lecturer in Nuclear Physics

Applications are invited from experimental or theoretical physicists with experience in nuclear structure research for a post of Lecturer tenable from August 1 1968

Salary scale £1 470 to £2 270 then subject to review, to £2 630 A £60 London Allowance plus F S S U benefit will also be payable

Details of facilities available, programmes of research, and teaching duties together with forms of application and conditions of appointment, may be obtained from the Registrar, King's College, Strand, London, W C 2 to whom completed forms should be sent by February 28, 1968 (37)

Scientific Civil Service

SCS

INFESTATION CONTROL LABORATORY

(Ministry of Agriculture, Fisheries and Food)

Tolworth and Worplesdon, Surrey

PHARMACOLOGIST/BIOCHEMIST (graded S S O /S O) required at Tolworth to initiate and undertake research on the pharmacological/ physiological actions of compounds with potential value as rodenticides (Reference S/52-53/MAF/67/5)

MICROBIOLOGIST (graded E O /A E O) required at Worplesdon to assist with research on myxomatosis Projects include laboratory studies of the virus system using tissue culture and immunological techniques Relevant experience desirable Some field work involved (Reference S/94-95/MAF/68/4)

CHEMIST or BIOCHEMIST (graded E O /A E O) required at Tolworth to take part in interesting biochemical work with a small team investigating the metabolism of pesticides in birds Experience of chromatographic techniques an advantage (Reference S/94-95/68/MAF/6) Closing date January 29, 1968

Non-contributory pension Promotion prospects

APPLICATION FORMS from Civil Service Commission, Savile Row, London W 1, quoting appropriate reference Closing date January 26, 1968, except where otherwise stated

REGIONAL PESTS SERVICE

(Ministry of Agriculture, Fisheries and Food)

BIOLOGISTS (graded E O /A E O) with training in Entomology required to work as Insect Inspectors at Newcastle and Nottingham and carry out field and investigation work on imported foodstuffs in store, during transport and processing, including assessment of nature of infestation, advice on control measures and supervision of their execution

Non-contributory pension Promotion prospects

APPLICATION FORMS from Civil Service Commission, Savile Row, London W 1, quoting S/94-95/68/MAF/5 Closing date January 26, 1968

ROYAL ARMY MEDICAL COLLEGE

Millbank, London S.W.1

PARASITOLOGIST (graded E O) required as principal technical assistant responsible for preparation of pathology class-room for practical classes, meetings and demonstrations involving human Protozoology and Helminthology, to maintain parasitological specimens and biological material for this purpose, to set out macroscopic and microscopic demonstrations, to prepare and annotate descriptive drawings and diagrams to support these demonstrations and to assist in the practical tuition in parasitology of medical officers and laboratory technicians Successful candidate may also undertake practical work in diagnosis of parasitic diseases and will have opportunities to participate in research Duties may include work with experimental animals

Prospect of permanent pensionable appointment

APPLICATIONS to Ministry of Defence, CE2(f)(AD), Northumberland House, Northumberland Avenue, London W C 2

SALARIES, QUALIFICATIONS and AGE LIMITS

SCIENTIFIC OFFICER/SENIOR SCIENTIFIC OFFICER

SALARIES (starting salary may be above minimum) S O £926–£1,574 (Increments and special £120 award for approved post-graduate experience)
S S O £1,744–£2,155 Most Scientific Officer Class appointments carry promotion prospects to Principal Scientific Officer £2,250–£3,107 Salaries are supplemented in the London area £125 Inner London, £75 Outer London

QUALIFICATIONS
S O 1st or 2nd class hons degree or equivalent or higher qualifications in appropriate subject Age under 29
S S O As above plus at least 3 years' post-graduate research Age normally 26–31

ASSISTANT EXPERIMENTAL OFFICER/EXPERIMENTAL OFFICER

SALARIES A E O £584 (age 18)–£803 (age 22)–£1,017 (age 26 or over)–£1,243
E O £1,365–£1,734 (starting salary may be above minimum) Most Assistant Experimental Officers become Experimental Officers before reaching A E O scale maximum Promotion prospects to Senior Experimental Officer £1,977–£2,411
Salaries are supplemented in the London area £125 Inner London, £75 Outer London

QUALIFICATIONS
Degree, H N C , or equivalent in appropriate subject Under 22, minimum qualification is G C E in five subjects, including two Scientific/Mathematical subjects at 'A' level or equivalent level
A E O age 18–27, E O normally 26–30

A free booklet entitled "THE SCIENTIFIC CIVIL SERVICE" is available on request from Civil Service Commission, Savile Row, London W.1. (42)

opportunities with Fisons

ORGANIC RESEARCH CHEMIST

We have a vacancy in our Chemistry Department for a male Organic Research Chemist holding a Ph D, aged 24–25 The position is a challenging one with ample scope and encouragement given for contributing new ideas to the creation of new synthetic pesticides Reference Serial Number 147/10

PHYSICAL CHEMIST

We have a vacancy in our Chemistry Department for a male graduate (age up to 25 years) holding a B Sc in Chemistry, and who is interested in studying the physical chemistry of newly synthesized pesticides. Reference Serial Number 148/10

The general conditions of employment and salary are good There is an excellent contributory pension scheme and an optional medical provident scheme The Research Station is situated in very pleasant country about fifteen miles from Cambridge and four miles from Saffron Walden Free transport is provided to and from Bishop's Stortford/Saffron Walden/Cambridge to Research Station There is an excellent subsidized canteen and encouragement is given to various sporting and social activities

Please write quoting relevant serial number, giving brief particulars of qualifications, to the

FISONS

Personnel Officer, Fisons Cambridge Division,
Chesterford Park Research Station, Nr. Saffron Walden, Essex.
Telephone: Saffron Walden 3542.

(33)

UNIVERSITY OF MALAYA

CHAIR OF CHEMICAL TECHNOLOGY
FACULTY OF SCIENCE

Applications are invited for a newly created Chair of Chemical Technology in the Department of Chemistry The appointee will be responsible for the organisation of a new four-year course in Chemical Technology leading to the degree of B Sc, with Honours, in the Faculty of Science Candidates should have considerable experience in research and teaching, and preferably also administrative experience The successful candidate is expected to assume duty approximately mid-1968, or soon thereafter

EMOLUMENTS (approximate sterling equivalents at current exchange rates)

(a) Salary There is a range of basic salaries, to one of which a Professor is appointed depending on his qualifications and experience These are £2 882, £2,980, £3,077, £3,175, £3,272, £3,370, £3 468

In addition, the following allowances are payable

(b) Variable Allowance 35 per cent of basic salary, subject to certain maxima depending on marital status, minimum £244 per annum, maximum £651 per annum

(c) Inducement Allowance (if awarded), up to £1,628 per annum (In exceptional cases an inducement allowance exceeding this amount may be granted)

HOUSING will be provided if available, for which a rent of £163 to £204 per annum will be charged

PROVIDENT FUND Staff member contributes 5 per cent and University 15 per cent of basic salary

Further particulars and application forms are obtainable from the Association of Commonwealth Universities (Branch Office), Marlborough House, Pall Mall London S W 1 The closing date for the receipt of applications in London and Kuala Lumpur is February 15, 1968 (43)

LUTON & DUNSTABLE HOSPITAL

LUTON BEDS

Applications are invited for the post of Biochemist (Senior Grade—Salary £1,833 to £2,276) in the Department of Clinical Biochemistry at the above Hospital The successful applicant should have had not less than five years' experience in the basic grade of Biochemist This modern Department provides a Central Laboratory Service for the whole of Bedfordshire and is fully equipped to cover most aspects of Clinical Biochemistry Further information concerning the post may be obtained from The Consultant Chemical Pathologist at the Hospital

Applications from Graduates or A R I C Members, giving full information of qualifications and experience, together with the names of two referees, should be sent to The Hospital Secretary (63)

LIBRARIAN

H J HEINZ COMPANY LTD require a Librarian aged 24 or above, qualified to A L A standard or in possession of suitable experience to maintain and develop the library services within the Company

The successful candidate, who will report directly to the head of the information department, will be responsible for book selection, classifying and cataloguing stock, loans from other libraries, maintaining journal subscriptions and circulation

The post is located at our new head offices and research centre in Hayes, Middlesex

Conditions of employment are those of a large, progressive company

Please write, giving brief career résumé to,

HEINZ 57

The Personnel Officer,
H. J. Heinz Company Ltd.,
Hayes Park,
Hayes, Middlesex.

(32)

UNIVERSITY OF DUBLIN

TRINITY COLLEGE

LECTURER OR JUNIOR LECTURER IN MYCOLOGY

Applications are invited for the above post Preference will be given to candidates with special interest in Soil Mycology

Salary Scales

Lecturer £1 400 by £60 to £1,700 (merit bar), £1,780 by £60 to £2 500

Junior Lecturer, £1,160 by £60 to £1,340

Marriage and children's allowances are paid, and there is a non-contributory pension scheme

Further information from the Secretary to the College Trinity College Dublin 2, who will receive formal applications up to January 24, 1968 (66)

UNIVERSITY OF OXFORD

JUNIOR LECTURESHIP IN MATHEMATICS (PURE OR APPLIED)

Applications are invited for a Junior Lectureship in Mathematics The appointment is for a period of three years from October 1, 1968, and is not renewable The stipend is on the scale £1,260 by £80 to £1 340 by £50 to £1 390 The post may also be held in conjunction with a Savic Junior Research Fellowship at Wadham College

Further details may be obtained from the Secretary of Faculties, University Registry, Broad Street, Oxford, to whom applications should be made not later than February 12, 1968 (36)

CHEMICAL ENGINEERING DEPARTMENT University College London, Gower Street W C 1, requires (a) Senior Technician and Technician to work on fluidisation experiments involving X-ray and photographic techniques Good practical experience of laboratory work with some photographic knowledge required, (b) Senior Technician and Technician to work on heat and mass transfer measurements in turbulent flow of dilute polymer solutions O N C /A level mathematics with some knowledge of chemistry required—Application forms from Establishment Officer, quoting CH/E/5 (41)

1967
THE QUEEN'S AWARD
TO INDUSTRY

(Bio) Chemists

The Organic Department at the Radiochemical Centre, Amersham, is responsible for the development and production of compounds labelled with carbon-14 or tritium using enzymatic synthesis or microbiological preparation to supply the growing worldwide demand for radiochemicals for use principally in university and medical research units The work involves laboratory scale development and manufacturing within a commercial environment and requires close contact with users in this country and abroad

A first class Biochemist capable of making a significant contribution in this field is required. He will be appointed as a Scientific Officer or, if in his late twenties with a record of significant work in a scientific environment, as a Senior Scientific Officer. Applicants should have a good honours degree and preferably a postgraduate qualification

A Chemist with HNC or a pass degree is also required to augment the staff working in this field Appointment as an Assistant Experimental Officer or Experimental Officer, according to age and experience, is proposed

Scientific Officer	**£995–£1,685**
Senior Scientific Officer	**£1,870–£2,310**
Assistant Experimental Officer	**£925 (at age 23)–£1,335**
Experimental Officer	**£1,465–£1,860**

Write for application form and further details, if required, to

The Personnel Officer (Ref S 126/34)

DIRECTOR OF MEDICAL COMPUTING SERVICES

HEALTH SCIENCES CENTRE

University of Alberta • University of Alberta Hospital

Plans are well established, at the University of Alberta, for the development of a Health Sciences Centre encompassing the Faculty of Medicine and the University of Alberta Hospital The development will have the benefit of a detailed study now nearing completion, by TRW Systems, Los Angeles

We are now ready to appoint a Director of Medical Computing Services who will build up a staff to establish a computing and information system in the Health Sciences Centre The Director will be responsible to the Dean of Medicine, and to the Executive Director of the University Hospital He will hold appointments in the Health Sciences Centre and, at the rank of Professor, in the Faculty of Medicine, and in the Department of Computing Science Senior members of the Director's staff will also hold academic appointments We are looking for a Director who has a Ph D and/or an M D, a research background, and experience in computing science in a hospital environment This is a key position with salary open

Interested persons are invited to send a curriculum vitae to

Professor R. S. Fraser,
Department of Medicine,
University of Alberta,
Edmonton, Alberta,
Canada.

UNIVERSITY OF BELFAST

SENIOR LECTURESHIP OR LECTURESHIP IN PHYSICS

The Senate of the Queen's University of Belfast invites applications for a Senior Lectureship or Lectureship in the Department of Pure and Applied Physics, School of Physics and Applied Mathematics, from October 1 1968 Applicants should have research experience (experimental or theoretical) in some branch of photon physics such as lasers, photo-electronics, image tubes, communications and information processing or physical optics Salary range for a Senior Lectureship is £2,605 to £3,415 plus contributory pension rights under the F.S S U and for a Lectureship £1,470 to £2,630 plus F S S U Initial placing on the salary scales will depend on qualifications and experience Applications should be received by February 5, 1968

Further particulars may be obtained from G R Cowie, M A, LL B J P, Secretary Queen's University, Belfast, BT7 1NN, Northern Ireland (25)

UNIVERSITY OF MANCHESTER INSTITUTE OF SCIENCE AND TECHNOLOGY

DEPARTMENT OF ELECTRICAL ENGINEERING AND ELECTRONICS

EXPERIMENTAL OFFICER

Applicatons are invited for the post of Experimental Officer in Electronics The duties attached to this post involve the operation and maintenance of a low energy electron diffraction apparatus Candidates should have a good knowledge of physics and previous experience of the fields of high vacuum techniques or electronics circuits is desirable

Commencing salary according to qualifications and experience in the scale £920 to £1,525 per annum Federated Superannuation System for Universities

Application forms and conditions of appointment may be obtained from the Registrar of the Institute, Sackville Street, Manchester 1, to whom completed applications should be returned by February 29, 1968 (47)

THE DEPARTMENT OF BIOLOGY, UNIversity of Calgary, Calgary, Alberta, Canada has Graduate Student Assistantships available in the areas of Comparative Animal Physiology, Developmental Animal and Plant Biology, Environmental Biology, Genetics Microbiology, and Plant Taxonomy Graduate Teaching Assistantships range from $1,840 to $2 800 for eight months (September to April) Graduate Research Assistantships range from $2,400 to $2,800 for twelve months Fees are remitted and travel assistance to a maximum of $250 is available Students holding eight-month assistantships are eligible to compete for Inter-Session Bursaries ($1,000) for the summer period —Inquiries should be addressed to the Head of the Department well before February 15, 1968 Completed applications must be received by March 1, 1968 (17)

THE DEPARTMENT OF PHYSIOLOGY and Pharmacology, Ontario Veterinary College University of Guelph, Guelph, Ontario, Canada requires four faculty members to meet growing teaching and research needs Persons interested in the following positions are invited to send curriculum vitae, grade transcripts, list of publications, and special qualifications and interests to Dr H G Downie, Professor and Head of the Department

1 D V M (or equivalent) with Ph D in Pharmacology Duties include participation in the team approach to teaching undergraduate and graduate Pharmacology, and research in areas of own interest Rank Associate Professor

2 D V M (or equivalent) with Ph D in Pharmacology, Toxicology, or Biochemistry Duties include participation in the team approach by teaching undergraduate and graduate Toxicology and Pharmacology, administrative supervision of a veterinary toxicology testing laboratory, and research and development in forensic analysis Rank Associate Professor

3 D V M (or equivalent) with Master's degree in any related science Duties include participation in the team approach to teaching undergraduate Pharmacology The candidate would be expected to pursue graduate work at the Ph D level in Pharmacology Rank Lecturer

4 PHYSIOLOGIST with Ph D qualification Duties include instruction in Physiology to Physical Education undergraduates and participation in a laboratory course on Human Physiology Consideration will be given to those individuals having a special research interest in respiratory or cardiovascular physiology Rank Assistant Professor

Moving expenses up to $1 000 will be provided for each position All salaries are competitive with industry (16)

NATURE Volume 217
JANUARY 13, 1968

Do the Universities have a Case?

Ever since the University Grants Committee was told two months ago what money there would be to spend in each of the next five academic years in Britain, individual universities have been complaining that they will not be able to make ends meet without serious and even crippling economies And on the face of things, of course, there is something in what they say. The rate of grant will be increased more or less in proportion with the increase in student population to be expected in the immediate future, but there is nothing to suggest that in the five years immediately ahead the universities will have the opportunity to make good some of the more glaring deficiencies of the present system—the lack of a research tradition in the newer institutions and the general skimping on postgraduate teaching which is now becoming commonplace Unfortunately, however, the universities are their own worst enemies when it comes to discussions of financial matters and in the past few weeks have foolishly and even wrongly declined to publish factual information about the prospects for the coming quinquennium, which is the only means by which the outside world can judge whether the complaints now being made are substantial and not just the public irritation of people whose budget applications have been cut down to size

The circumstances are these The University Grants Committee announces at the beginning of each quinquennium how much money it will have to spend on financing the universities, but it is for universities themselves to decide whether to make public their own share or prospective share On this occasion, the Universities of Oxford and Cambridge have made a clean breast of their prospects, partly no doubt because their forms of university administration make it necessary that information like this should be publicly conveyed to the academic body Elsewhere, however, universities behave as if this information is and should be secret to themselves Sometimes a vice-chancellor in making a public complaint will let slip the fact that the allocation for the coming year is 1 per cent, or 2 per cent, or x per cent greater than in the present Sometimes a university will agree that this information should be made available after it has been through the mill of discussion in the senate Sometimes universities behave as if they intend to keep the details secret for as long as possible in much the spirit that private individuals choose not to make public information about their bank accounts The absurdity, of course, is that the University Grants Committee will in due course make public the details of its allocations to all the universities In future, no doubt, the decision that the universities as a whole should be made publicly accountable will lead to the publication of much more detailed information about the working of universities, and about the methods by which they obtain and spend their money, than has ever been available in the past The universities may enjoy trying to shut the stable door, but they ought to know that the horse is certain to bolt in the end

There are several reasons why these policies are mistaken and should be changed For one thing, the financing of the universities has become a matter of immediate public importance and it is wrong that the University Grants Committee should seek to perpetuate the fiction that its dealings with individual universities are entirely private matters After all, the committee is the first to solicit public support or at least discussion at times when it feels that too little money is being spent on the development of the universities The time has also come when it should recognize that the country as a whole has a right to ask not merely whether the scale of the whole operation is right, but whether more detailed aspects of the policy on the universities are being handled properly Are some categories of universities getting too large or too small a share of the cake ? Is the University Grants Committee itself as zealous as it should be in trying to spend as much of its money as possible in those institutions which have a proven record for efficiency ? Is the geographical distribution of university money fair ? Are the colleges of advanced technology getting a fair crack of the whip ? The time to ask these questions is when decisions are being taken about the allocation of funds When the money has been spent, it is too late It is true that the University Grants Committee may well argue that a bald statement of how it proposes to allocate its funds may be misleading, for there may be considerable fluctuations from year to year in the cost of operating individual universities which arise not from broad issues of policy but from accidental causes, one university may have to equip a new laboratory, for example, and the cost may fall predominantly in one year or one quinquennium But this is not an argument for no information but, on the contrary, a reason why the announcement by the University Grants Committee of its plans for the coming quinquennium should be accompanied by a full statement of the reasons why its decisions have been made The cryptic character of its customary behaviour is merely one of the reasons why politicians and others have been provoked into believing that a much tighter method of controlling the universities is overdue

If the coyness of the University Grants Committee is mistaken, that of individual universities is downright self-destructive. For one thing, it is a means of hampering intelligent public discussion of the running of universities, both among the academics most directly concerned and in the outside world It is true, of course, that those who belong to the right committees will sooner or later be given detailed statements of how much or how little money there is to spend, but this is no substitute for the awareness among the teaching staffs of universities of the ways in which their operations are necessarily circumscribed by financial considerations. Internally, the consequences can be quite serious. What sense is there in universities' attempts to operate more efficiently and economically if those who will have to save the pennies are not kept fully informed? And how can academics be expected to form sensible opinions about the long-term strategy for the development of the university to which they belong if the details of now much money there is to spend are regarded as the privileged possession of a handful among them? Outside the universities, however, the consequences of this coyness are even more alarming. In effect, the universities by their pointless gentility are prevented from making the full-blooded claim on public sympathy which their objectives would justify.

What is to be done? The universities themselves could do a lot to help and, if the University Grants Committee is unwilling to make an intelligent comment on quinquennial allocations as these are made, the Committee of Vice-Chancellors and Principals could well take over that task. But in the long run, the real need is somehow to suppress the feeling among university administrators and even academics that there is some virtue in keeping silence about the ways in which money is spent. So long as universities were private institutions and so long as the numbers of people with whom they dealt were so small that their influence in the economic life of Britain could be neglected, this may have been a tenable position. But the need now is for a much more open conduct of affairs. Since it is public money which is being spent, the universities would be prudent to remember that if they do not voluntarily provide information which is of great public importance, matters may be taken out of their hands.

Public Transport should be Practicable

THIS looks like being a decade in which governments will be preoccupied with issues of public transport, at least in Britain and the United States. After many years of speculation and timid experiment in urban planning, it has now been borne in on a great many people that it is not feasible to plan the shape of cities without at the same time planning the transport networks by which people will move or seek to move from one place to another. In Britain, the issue has been made controversial as well as topical by the energetic way in which Mrs Barbara Castle, Minister of Transport for more than a year, has been reshaping the administrative structure of public transport. The starting point for the policies which will obviously flow freely in the years ahead is the White Paper *Public Transport and Traffic* (HMSO, 3*s* 9*d*). Even Mrs Castle's critics have been compelled to admit that this is a formidable and even admirable document. One of its striking and least assailable conclusions is that public transport should be organized on a local basis, not centrally, which will frequently mean the transfer of large parts of existing transport undertakings to local passenger transport authorities, but which will also on some occasions entail that bus companies at present operated by comparatively small local authorities will be swallowed up by larger units. One important innovation is that passenger transport authorities will be required to assume some responsibility for the pattern of railway services, particularly where these are widely used by commuters, and no doubt the time will come when these passenger transport authorities find themselves paying subventions to the central railway authority for the cost of maintaining public services which would otherwise be uneconomic. It is, of course, entirely sensible that the costs of subsidies like this should be felt directly at the local level at which they arise, and that machinery should exist for making comparisons between the social benefits that can be obtained by investing a sum of money in alternative means of transport. The doubts which Mrs Castle's scheme arouses are not doubts of principle but of practice. What prospect is there that the passenger transport authorities established at a local level will be able to seize the opportunities which transport technology now promises? How well will they be able to integrate their policies for the development of public transport with policies for the shape of urban planning under the control of other authorities? How far will they be able to rise above the parochial considerations which bedevil local government in Britain?

The trouble is that there are now a great many conflicting claims on the attention of those who would more effectively exploit the technology of modern transport. The Ministry of Transport itself has recently been acquiring a commanding expertise in the economics of transport systems, and there is obviously a great deal to be done in the improvement of the efficiency of transport by persuading the users of the transport system to make demands on it which can more easily be satisfied. The danger here, however, is that too great a concern for pricing systems may lead to policies which are aimed at "pricing the motor car off the roads" when the real objective should be to make the most efficient use of the transport system as a whole—trains, buses and private cars included. The force of this argument was well put recently by the Standing Joint Committee on the Buchanan Report which is being sponsored by the engineering institutions.

United States Science Examined

As this issue of *Nature* went to press, the OECD was beginning its confrontation with the United States authorities on the report about the condition of science in the United States which has been prepared by the team of examiners which has been at work on the problem for the best part of two years The study is the eighth to have been carried out in the series of studies of national science policies in the 21 member nations of the OECD, but the chances are great that the special circumstances of the United States will bring up questions which earlier reports in the series have not raised Prominent among these are likely to be questions related to what is sometimes called the technology gap—a cause known to be close to the heart of the OECD. Not merely is there likely to be a serious attempt to draw from American experience in the management of science and technology, but there is also likely to be some attempt to determine the wisdom of trying to follow in Europe some of the developments which have been prominent in the United States in recent years

The OECD report, which is the basis for the discussions being held in Paris, has been prepared partly by the secretariat of the OECD and partly by a panel which consists of Dr H G B Casimir, director of the Philips Research Laboratories at Eindhoven; Mr Theo Lefevre, a former prime minister of Belgium, M Pierre Masse, chairman of Electricité de France, and Professor C H Waddington of the University of Edinburgh A full summary of the review of United States Science Policy, together with an account of the confrontation in Paris, will appear in *Nature* next week.

Drugs' Dark Days

The United States pharmaceutical industry must be suffering from a bad case of nostalgia The good old days of the nineteen-fifties—when wonder drugs brought wondrous profits and gratitude from the public as well—are probably gone for ever Instead, the federal government is getting more and more inquisitive about the whole business of medicines how much they cost to make, whether they perform as advertised, whether those with melodious trade names are better healers than those with clumsy generic names Two Senate investigations are now in progress, one looking into possible abuses in the diet pill industry, another into the pricing policies of drug manufacturers The total government spending on drugs by federal, state and municipal authorities continues to increase—it is now $200 million a year—so that the authorities are now unlikely to relax their vigilance

The aura of suspicion created by Senate investigators was even blamed by an executive of one of the pharmaceutical firms found guilty last week for conspiring to control the production and sales of tetracycline Certainly the jury had a lot to contend with—patent law, chemical formulae, patent and anti-trust laws were all freely quoted during the trial Their finding that three companies—Charles Pfizer and Company, American Cyanamid Company and the Bristol Myers Company—are guilty of criminal conspiracy in monopolizing the manufacture of tetracycline until 1961 has shaken the industry The decision, if it is not reversed, opens the door to lawsuits from major purchasers of tetracycline from the defendants The City of New York and the State of Florida have already filed their suits in the hope of recovering the treble damages allowed by the Sherman Anti-Trust Act against companies convicted of monopoly The sums eventually paid back to irate customers could exceed those awarded a few years ago when some American electrical companies were convicted of price-fixing

The industry, not surprisingly, feels hard done by The big laboratories, as the argument goes, bear the costs of all the research and, as soon as they come up with something useful, smaller companies rush in, copy the medicine and sell it at cut-prices Are the better-known branded products more efficacious? The big companies say they are, and many doctors, including some from the American Defense Department, which has been buying low-priced tetracycline from Italy rather than the expensive domestic brands, agree The Food and Drug Administration set up a special committee to study the problem of efficacy and equivalence, and the job is harder than anyone had thought. After eighteen months, the committee has asked for more time

The debate has really just begun Last year in Congress Senator Long of Louisiana tried to make it mandatory for all public agencies in the medicine-buying business to buy drugs by their chemical rather than by their trade names He failed, but a vestige of his wish survived in the form of a directive to the Department of Health, Education and Welfare to ask all state governments to promise that the medicines that they were buying for people on relief rolls was purchased at the lowest possible cost At the very least, this means that more attention will be paid to the question of getting best buys The price differences between what are said to be equal quantities of the same compound are staggering The Senate is hearing that public agencies were charged $2 09 in one case and $160 in another for the same quantity of reserpine tablets, and the Justice Department's complaint in the tetracycline case was that antibiotic tablets costing $2 or $3 a hundred to produce were being sold to the customer at $51 a hundred

Meanwhile, the FDA is getting ready to make public the results of its inquiry into the efficacy of medicines sold in America between 1938 and 1962, when stricter standards were established The advance reports say that about 10 per cent of the old favourites in the medicine cabinet could be denounced as worthless and some may have to be withdrawn from sale

Computers More Expensive

International Business Machines last week announced increases in the cost of both buying and renting its computers in Britain Renting an IBM machine will cost 10 per cent more, while buying one will cost up to 10 per cent more The hiring of time at computer bureaux and data centres will go up by between 3 and 10 per cent, and maintenance charges will increase by 4 per cent These increases, a response to the devaluation of sterling, may well be duplicated by other computer companies which use a large proportion of imported parts—a group which includes every computer manufacturer in Britain, with the possible exception of International Computers and Tabulators

IBM has also taken the opportunity of announcing a new computer, as part of the 360 series The new model, the 360/25, falls between the smallest machine in the IBM range, the 360/20, and the next up, the 360/30 It will offer users of the 360/20 a chance to increase their computing power without having to learn a new language, and competitive pricing should help to encourage buyers These moves come at a time of unprecedented weakness for IBM in the British market—it has even been suggested that IBM's share of the British market has fallen below 30 per cent Whether or not this is true—IBM always refuses to divulge its market share—it is certainly true that Britain is proving a tougher market than some others Because IBM does most of its production for Europe in France and West Germany the effects of devaluation are likely to hit the company harder than others Honeywell, which produces computers at its factory in Scotland, will be cheered by devaluation ICT, on the other hand, still views the effects of devaluation with some suspicion Colonel A T Maxwell, chairman of the company, presenting the annual report for 1967, said that the effect of the measures was still not clear "We are inevitably faced with higher costs, but we shall so direct our affairs as to contain these as much as possible We are also seizing the opportunity of increasing our exports "

Only one other computer manufacturer, Burroughs, has so far announced price increases of its own, they will work out at an average of about 7·5 per cent So far, no other companies have followed IBM and Burroughs, but the betting is that some—perhaps including English Electric—will have to do so within the next few weeks

Policy for Research

The British Government will shortly be issuing a long-awaited White Paper on research policy At least one of the purposes of the White Paper will be to define ways in which the research establishments can help industry Because there is plenty of room for disagreement—and misunderstanding—between the ministry and the industries it is trying to assist, the Electronic Engineering Association has got in first by producing a memorandum which sets out its own views on what the relationship should be The report, which goes for discussion to the Development Council for the Electronics Industry next month, may differ in emphasis from the policy which the ministry must by now have agreed on So far, though, any clashes between the association and the ministry are hypothetical

The chief point which the report makes is that, when projects are jointly undertaken by government and industry, leadership should be very firmly in the hands of the industrial partners Captain R. A Villiers of the association points out that when research establishments were involved with military work they kept closely in touch with the military market, but the shift to civil work means that a new relationship with industry has to be worked out. He thinks that the ministry has much to learn by examining the records of other industrialized countries, which tend, among other things, to contract more work out to industry and to do less in the establishments The main part the establishments can play on their own, he thinks, is in more basic research work—like, for example, the work on oceanography at Harwell.

Another idea which Captain Villiers puts forward involves the actual transfer of people from the establishments to industry and vice versa Teams of people from the establishments should be able to join industrial firms, and teams from industry should be seconded to government establishments to pick up know-how To do this, he says, both sides must become more flexible about transferring pension rights But so far he seems confident that there is no clash of views between himself and the Government Others will await the White Paper before committing themselves so cheerfully.

Swiss Smelting

The Swiss Aluminium Company has submitted a tender to build an aluminium smelter in Britain The company says the smelter could be built in 2 5 years at a cost of between £18 and £20 million and a maximum capacity of 100,000 tons Other tenders have so far been made by Rio Tinto Zinc in conjunction with British Insulated Callender's Cables, by Alcan Aluminium of Canada and by British Aluminium British Aluminium is jointly owned by Reynolds Metal Company of the United States and by Tube Investments.

The high cost of electricity in Britain has hitherto prohibited the development of a native aluminium smelting industry of any size The decision by the British Government to invite tenders for a plant was made with the intention both of reducing imports and of creating new jobs in development areas. Tariffs being out of the question, the project is rendered commercially viable by the offer of cheap electricity and generous investment grants (see *Nature*, **216**, 109, 1967) The Board of Trade is prepared to grant these incentives to foreign and British companies without discrimination The Government envisages the construction of two plants with a total capacity of 240,000 tons a year It is hoped that the first will begin production in 1970 and the second in 1974

Sediments for Peace

The Parliamentary Group for World Government, which is based in London, seems well launched on its campaign to bring international law and order to the bottom of the deep oceans Earlier this week the group made public the membership of the committee which has been formed to study some of the problems of arranging that the resources of the deep oceans should be exploited "for the benefit of all mankind" The chairman of the committee is a barrister, Mr Maurice Bathurst, and the ordinary membership seems equally divided between lawyers, scientists and those with more general interests Lord Ritchie-Calder is perhaps most accurately described as the founder member of the movement, for he was one of the first to urge, a year ago, that there should be a United Nations agency empowered to exploit the resources of the oceans and to spend the proceeds on international peace-keeping forces Other members include Dr G E R Deacon, director of the National Institute of Oceanography, Commandant Cousteau, director of the Institut Oceanographique at Monaco, Dr T. Gaskell, of British Petroleum Ltd, and Mr Oscar Gugen of the World Underwater Federation Dr Thor Heyerdahl has promised his support to the committee, which has already met on two occasions and which is evidently prepared for a busy year ahead

By all accounts, the committee will have to divide its time between the discussion of general principles and the lobbying of other interested—or uninterested—parties. The response of the last General Assembly of the United Nations to the request of the Maltese delegation that there should be set up an agency to organize the exploitation of the ocean beds was to establish, on December 20, a sub-committee to study the problem. Advocates of the peaceful uses of ocean sediments are not sure whether this is merely a device for putting off a decision about the formation of an international agency, although it would have been unreasonable to expect that the General Assembly could create an agency which raises all kinds of new problems in international law, and which may be financially hazardous as well, without satisfying itself that there is a feasible task to be accomplished. Nevertheless, there are some, at least, who fear that a committee with more than a score of nations as members will serve as a splendid cloak behind which the nations which fancy their own chances in the exploitation of the sea will be able to block agreement.

At this stage, however, nobody seems inclined to make light of the problems. Strictly academic problems are formidable enough. How, for example, to distinguish between the continental shelf and the deep sea ? The committee has apparently given some thought to a measurement of the thickness of the crustal layer as a definition, though some oceanographers would no doubt have interesting reservations to make on that. There are also questions such as whether a treaty which reserved the right of ocean exploration to an international agency should cover the extraction of minerals from seawater as well. But technical problems are insignificant compared with the legal obstacles yet to be fully defined. Freedom of the high seas in the most literal sense is clearly in jeopardy. The question of what to do with any profits from international exploitation is obviously another teaser, although the advocates of an international agency seem at this stage more concerned that there should be profits of some kind than that there should be agreement in advance on the distribution of the profits between peace-keeping, aid for development and other good causes. The committee has a good point when it urges that if an international agency is to be formed at all this should be done before national activities have established awkward precedents. Plainly it is undismayed by the slow start there has been on ocean mining.

Unlucky Strike Again

Mr Robert L. Strickman, the inventor of a new type of cigarette filter, announced last week his intention of robbing Columbia University of the privilege of developing the filter. The university, to which most of the rights in the filter were assigned, seems likely to dispute this decision and an acrimonious battle through the courts may be in the offing.

Mr Strickman claims that his filter is much more effective than other types both in removing tar and nicotine and in allowing the taste of the tobacco to come through. Wishing to have the filter tested, developed and licensed by a non-profit institution, Mr Strickman offered the rights to Columbia University. In July of last year, Columbia conducted a press conference, the timing and manner of which were widely criticized, to announce its acceptance of Mr Strickman's offer (*Nature*, **215**, 339; 1967). The university was at that time about to launch a campaign for raising funds of $200 million, and the potential income from licensing the filter was undoubtedly a principal factor in its decision. Critics, however, questioned the propriety of an academic institution making money in this way, and pointed out the risk the university took in creating the impression that it condoned or thought innocuous the smoking of cigarettes.

The advisability of its decision apart, Columbia is clearly determined to put the filter through the most stringent tests it can devise. Here lies the point of disagreement with Mr Strickman, who considers that enough testing has been done and that Columbia should have already begun licensing the filter to cigarette manufacturers. Although Mr Strickman is pressing for the return of his rights, he still wishes Columbia to share in the profits from the sale of the filter. The question now is whether Columbia will be able to accept even that truncated connexion with the filter.

Underdeveloped Trade

The Overseas Development Institute has ventured into a new field with its guide to *The Less Developed Countries in World Trade* (ODI, 30*s*.), written by Michael Zammit Cutajar and Alison Franks and published this week. The institute has studied the two-way process of trade for the first time, having previously concentrated on the one-directional flow of official aid and private investment to less developed countries. The trading problems of the less developed countries were examined in detail at the three month United Nations Conference on Trade and Development (UNCTAD) in 1964, and a second UNCTAD conference on the subject is to begin in New Delhi on February 1. The institute, an independent non-government body which promotes wide development overseas, hopes that the study will provide background information on the trading problems of the underdeveloped countries which form the majority of UNCTAD. The UNCTAD secretariat has co-operated in the compiling of the guide, although the idea for it came from members of the institute.

Before giving world trade figures and details of the exports of less developed countries, the guide puts forward the fundamentals of economic theory to explain the need for trade. Development cannot be achieved efficiently by either trade or aid alone, and situations are described in which each is most appropriate.

In the 12 years to 1965, world trade has increased by 135 per cent, but during that time the share of the less developed countries has fallen by over 7 per cent, to less than 20 per cent of the total. When exports are divided into two groups—primary commodities and manufactures—the less developed countries are found to be dependent on the first group, which accounts for 86 per cent of their export earnings. Developed and less developed countries each export about 42 per cent of the world total of primary products, but when it comes to manufactures the development gap is clearly seen. Developed countries export 80 per cent of the world total, while the share of the less developed countries stands at 6 per cent. The guide discusses the current demand for primary products and gives details of international agreements which are in force. Eleven primary products, ranging from petrol and metals to tea and coffee, are discussed in detail in terms of the nature and importance of the product, countries of supply, importing areas and national production figures, and the state of the market. British, United States and Common Market policies for trade with the less developed countries are discussed with a mass of information on the trade of the countries concerned. The guide concludes with a résumé of the work of the UNCTAD board and committees, and makes three proposals—a cocoa agreement, a scheme for tariff preferences for less developed countries and a scheme for supplementary financial measures, which could well be important talking points at the New Delhi meeting next month.

No Change at Caltech?

THE annual report of the president of the California Institute of Technology for the academic year now past provides the usual detailed and absorbing account of the institute's recent achievements. Although, this year, Dr Lee DuBridge has much to say about the launching of the institute's public appeal for $85 million, his account of events does less than justice to the questions increasingly being asked among the faculty at Pasadena and their contemporaries elsewhere—is the pursuit of excellence, or pre-eminence, as Dr DuBridge calls it, in conflict with the educational needs of the undergraduates, now almost outnumbered by the faculty?

Dr Lee DuBridge, president of the California Institute of Technology.

Like many other institutions, the California Institute of Technology is the continuing victim of what is now called sophistication. Simply staying still costs an extra 6 or 7 per cent a year. The institute wants to spend some of the $85 million which it hopes to raise on new buildings, while some of it will be added to the endowment, which amounted to a comparatively modest $129 million in 1967. Within the running budget, which included expenditure of $30·35 million in 1967, federal research plays a prominent part. Thus the direct cost of federally sponsored research worked out at $11·22 million, compared with $9·24 for what is described as "instruction and research". In practice, the institute seems not too heavily dependent on any one agency for its funds—the US Navy provided $2·13 million and the US Air Force $1·74 million in 1967, with roughly comparable amounts from the Public Health Service ($3·21 million), the AEC ($2·69 million), the NASA ($2·17 million) and the NSF ($2·01 million). It should fare as well as any other institution if, in the months ahead, there is a sharp reduction of the scale on which federal funds are made available. Whether the institute will be affected indirectly by the straitened NASA budget in the years ahead is another matter, for annual expenditure at the Jet Propulsion Laboratory which is managed on behalf of federal agencies by the institute grew by less than 1 per cent (to $248 million) between 1966 and 1967, and could conceivably decline in the years immediately ahead.

Financial considerations have not, however, impeded the sustained if modest growth of the institute in the recent past. The faculty, for example, has grown from 515 to 600 in five years, with the number of full professors almost unchanged at 142 but with a rapid increase from 159 to 206 in the number of research fellows. The intake of undergraduates, by contrast, has been constant for some years at 200 or so, but outsiders will be a little surprised that the rate of application for entry is only five times as great. Drop-outs account for 39 per cent of the student body over a four year undergraduate course, though no doubt some of these people complete their undergraduate degrees elsewhere. No doubt the rate of dropping out will be taken merely as a proof that even the more rigorous processes of selection cannot be a cast-iron assurance of academic success. At Caltech, as the Swann Committee has found in Britain, however, academic success begets academic temperament. Thus the production of PhD degrees is running at about 100 a year, and has not yet been much affected by the increase of the graduate school from 660 to 770 in the past three years. In 1967, for example, 70 per cent of those graduating with PhD degrees found jobs at universities or at research institutions.

Decline of Bone Strontium

A CONTINUING decline of the concentration of radioactive strontium in human bones in the British Isles is recorded in the most recent of the reports on the subject by the Medical Research Council (*Assay of Strontium-90 in Human Bone*, HMSO, 3*s*.). The results are based on analyses carried out separately by the UK Atomic Energy Authority and by a group based on Scottish hospitals. Bone samples were obtained from the vertebrae of individuals dying between July and December 1966, and the results obtained by the two groups are shown in the following table.

	UKAEA		Glasgow	
	1965	1966	1965	1966
Newborn and stillborn	2·5	2·2	3·4	2·7
Under 5 years (excluding newborn)	6·7	5·1	8·2	6·5
6–23 months	9·1	6·2	11·0	8·3

This accords well with the measurements of the concentration of radioactive materials in the atmosphere and in rain which have now been published by the Health Physics and Medical Division of the AERE, Harwell. The report (HMSO, 7*s*.), which runs up to the middle of 1967, shows that the average concentration of strontium-90 in rainwater had decreased by roughly 40 per cent between the first half of 1966 and the first half of 1967. Because rainfall in 1967 was considerably less than in the previous year, the actual deposition of strontium-90 in the first half of 1967 was only 40 per cent of that deposited in the same period during the preceding year. By the end of 1966, it seems as if the rate of deposition of fresh strontium-90 had become comparable with and smaller than the rate of disappearance of deposited strontium-90 by means of radioactive decay, so that "for the first time", the "cumulative deposition began to decrease with time". The balance was reversed with the spring rains in 1967, but it is clear that an end is in sight to the accumulation of radioactivity in the soil.

All Quiet on the Quiet Sun

LIKE a great actress in later life, the organization of the International Years of the Quiet Sun is now well settled in the habit of making its final appearance. Formally, it is true, the great symposium at Imperial College last July marked the end of the period of co-ordinated or at least simultaneous observation. Now there has appeared the latest issue of *IQSY Notes*, the twenty-first, which is full of valedictory statements and which also contains the announcement that this issue will be the last. The next step is the publication of the *Annals of the IQSY*, which is being managed by the Royal Society. There will be admiration and even gratitude for the firm promise that the first of the eight or nine volumes in this series will appear early this year, and that publication of the whole series—which will include a record of the symposium last July—should be complete by the end of 1969. With luck, it should be possible to avoid overlap between the productions of the IQSY and of Dr Herbert Freeman's Commission on Solar and Terrestrial Physics, now in the process of gestation.

Although the latest *IQSY Notes* has no great surprises, it does provide some information about the financing of international operations like these. It is notable that the total cost of administering the IQSY for a period of 5½ years amounted to merely $173,000—a sum which had to cover the maintenance of the secretariat in London, the publication of manuals and the organization of meetings. The publication of the *Annals* is reckoned to cost a further $60,000. Most of the funds have been raised by voluntary contributions from the national committees of participating countries. The statement of the council goes out of its way to emphasize that "the payment of a contribution has never been a condition of adherence to the IQSY programme. Contributing and non-contributing committees have been treated exactly alike. . . . This was essential, since the prime objective of the scientific programme was to encourage the widest possible geographical participation in the programme. . . ." This decision was no doubt wise, for the list of contributors suggests that some participants have been rather slow in paying up. It is perhaps understandable that Taiwan and the Congo should not have paid after the first year or two. It is more surprising that Belgium, Finland, Israel, Rumania and Switzerland should not have contributed after a similar period. The Soviet Union had only paid two contributions out of six by October last year—a total of $10,000. Difficulties about the convertibility of the rouble (and of the rupee) are known to have been a complication in this connexion. But the IQSY seems to have managed well enough and, even if its scientific programme was inescapably a somewhat undramatic business, the organization may well have been able to establish standards of good management among international organizations.

More Medical Science

A SMALL reform in the organization of the British Medical Association seems likely to come about as a result of suggestions made by Dr Ronald Gibson, chairman of the council of the association. Dr Gibson has proposed that all the scientific and educational work done by the BMA should be brought under the umbrella of a central board. As well as the work of the present Committee on Medical Science, the board would provide for scientific and sociological work. But the hope expressed by Dr Gibson that the BMA could in this way "prove its right to be considered a forceful entity in the field of medical science" is hardly realistic. The proposal does not recommend any increase in the money which the BMA spends on research—last year it was £60,000—but simply concentrates on the reform of the committee structure. Nor is the suggestion particularly new—a similar idea was put forward some years ago. Dr Gibson has suggested that if the board is set up—a decision which the council of the BMA will have to take within the next few weeks—it might also sponsor some general sociological surveys. Topics put forward include drug addiction, the population explosion, nutrition, the stress diseases and the like.

There seems to be no reason why the council should not approve the suggestion, modest as it is. It may, however, put the BMA into a position where it could begin to influence medical research in Britain, given a greater financial outlay. A counterweight to the massive influence of the Medical Research Council would not be entirely unwelcome. The field where the BMA might be most influential, clinical research, has not so far had the same attention in the MRC as more basic studies, although this may change when the MRC Clinical Research Centre opens at Brent Hospital in 1970. In the BMA, the move reflects a feeling that the politics of medicine has in the past few years been allowed to obscure the more cerebral activities of the BMA. Having exhibited its taste and talent for political controversy, the argument runs, the BMA should now try to divorce itself somewhat from the image of a militant, if successful, trade union.

The American Medical Association itself turned to research for many of the same reasons several years ago. There was a feeling that the AMA had become too closely identified with the fight against the Medicare proposals, and too far detached from scientific research. But the move to support basic research, in the Institute for Biomedical Research at the AMA headquarters in Chicago, seems not to have been wholly successful. After only two years of existence, the institute is now to have its third director—George W. Beadle, the retiring president of the University of Chicago. (His predecessors were Dr Roy E. Ritts and Sir John Eccles.) The AMA has also decided to move the institute to a new site on the campus of the University of Chicago. Unless the BMA decides to spend a good deal more on research, however, it is unlikely to be troubled by problems such as these.

Doctors' Complaints

THE career structure of the medical profession in Britain is an important stimulus of the emigration of doctors and an effective deterrent to their return. This is one of the conclusions reached by an interview board sent by the Ministry of Health to the United States and Canada last October and which has now reported its findings. (*British Medical Journal*, i, 45; 1968.)

Between 1962 and 1964 the rate of emigration of British doctors to all countries was about 300 a year—more than one-sixth of the annual output of British medical schools in those years. This rate of emigration, which there is no reason to suppose will have diminished in subsequent years, was the goad to the board's departure. Having advertised its coming in various medical journals, it was able to interview 135 out of the 200 doctors who applied to it, with the purpose both of finding them jobs in Britain and of ascertaining why they had left and what impediments they saw to their return. Fifty of the doctors whom the board interviewed have already been offered, and have accepted, appointments in Britain and it is expected that more will do so.

The board discovered a fairly consistent picture of dissatisfaction with the National Health Service and its doings. General practitioners who in Britain had aspired to a specialist career gave as their reason for emigrating the lack of hospital facilities for doing major surgery and other specialized practice, and the waiting period for senior posts after the appropriate higher qualifications had been gained. Other reasons for emigrating were the paucity of senior academic posts in the United Kingdom and the relative scarcity of research funds. To the board's regret, it found that an emigrant's decision to leave was not always a purely personal one: "evidence of British consultants and professors advising and encouraging trainees to emigrate because of the uncertainty of their prospects and the rigidity of the National Health Service and academic structure in the United Kingdom was unfortunately forthcoming".

For those who wish to return to the United Kingdom, the most formidable obstacle is the insistence by the National Health Service that candidates attend an interview. If unsuccessful the candidate is left with his travelling expenses to pay, and if successful he is faced with removal costs of his dependants and effects as well. In this instance the board was empowered to reimburse such costs, which may account for much of its success in attracting doctors back. Other impediments to a return are the lack of information about jobs, the hostile attitude of the North American press, and its British element in particular, towards the National Health Service, and the lack of any accepted equivalence between the higher qualifications awarded in North America and in Britain.

One reason for the board's success may have been that it was less scrupulous in selecting candidates for interview than other interview boards have been. It recommends that the obstacles to return should be reduced, and that to diminish the rate of emigration in future the arrangements for career guidance of trainees should be improved and that more opportunities should be created for academic careers. The Minister of Health is now studying these recommendations.

The loss of 300 doctors a year is indeed serious, but should be seen in proportion to the numbers Britain gains from other countries. Last year almost 2,000 doctors from the Commonwealth alone applied to enter Britain. In 1965, the most recent year for which figures are available, there were 6,000 doctors working in National Health hospitals who had been born abroad—about 30 per cent of the total. Of general practitioners 2,600, or 12 per cent of the total, were born abroad. If every doctor were to practise in the country of his birth, Britain would not be the gainer. But this is not to decry any efforts that the ministry may now make to encourage the return of expatriates, and to allay the discontent of those who would follow them.

More on Asbestosis

THAT there are risks associated with asbestos is not now disputed. A review of the problem as it occurs in Britain has just been published as a memorandum by the Advisory Panel on Problems Arising from the Use of Asbestos (HMSO, 3*s*. 9*d*.). The advisory panel, set up in 1965 by HM Factory Inspectorate, is responsible for considering the use of asbestos in relation to the health of those directly or indirectly exposed to asbestos in their occupations. Over the whole country the panel estimates that about 20,000 persons are exposed to asbestos in the use or handling of the fibres. The figure is probably higher than this; people can easily be put at risk by working near to where asbestos is handled. The present Asbestos Industry Regulations, 1931, are applied to some 300 registered factories, but the report says that there are many other factories which use asbestos products and which do not come within the regulations. The Ministry of Labour is at present drawing up new regulations to cover a wider range of factories.

It was in the 1920s that it was first clearly recognized that asbestosis, a fibrotic condition of the lungs, is caused by occupational exposure to asbestos. Within a few years it was suggested that the disease might be complicated by the development of carcinoma of the lung, but an association was not generally accepted until the 1950s. Recently, there has been concern over the occurrence of mesothelial tumours of the pleura or peritoneum which appear to be causally related to asbestos exposure in many cases. Since 1966 mesothelioma has been a scheduled industrial disease.

The advisory panel concludes that there is an increasing incidence of asbestosis in the country. The most likely explanation for this increase is the greater use of asbestos and the greater numbers of people employed in the industry over the past 20 years. But the panel says that "there is no evidence that the overall attack rate has decreased in the industry over this period, although it has in some textile mills in which the dust conditions have been greatly improved". It appears that if the regulations are more widely and more stringently applied than at present, the number of cases should inevitably fall.

The panel indicates that crocidolite has a special significance in relation to mesothelial tumours. It recommends that other types of fibre should be substituted for crocidolite wherever possible, and, where this is impossible, special precautions should be taken to reduce the risks of inhaling the material. The panel admits that at the moment the level of exposure below which the risk may be negligible is not known. The quantity of crocidolite (blue asbestos) imported into the country is much less than the other varieties of asbestos, and it has remained at about 7,000 tons per year for the last few years. But time may show that other fibres are also implicated in the development of mesothelial tumours.

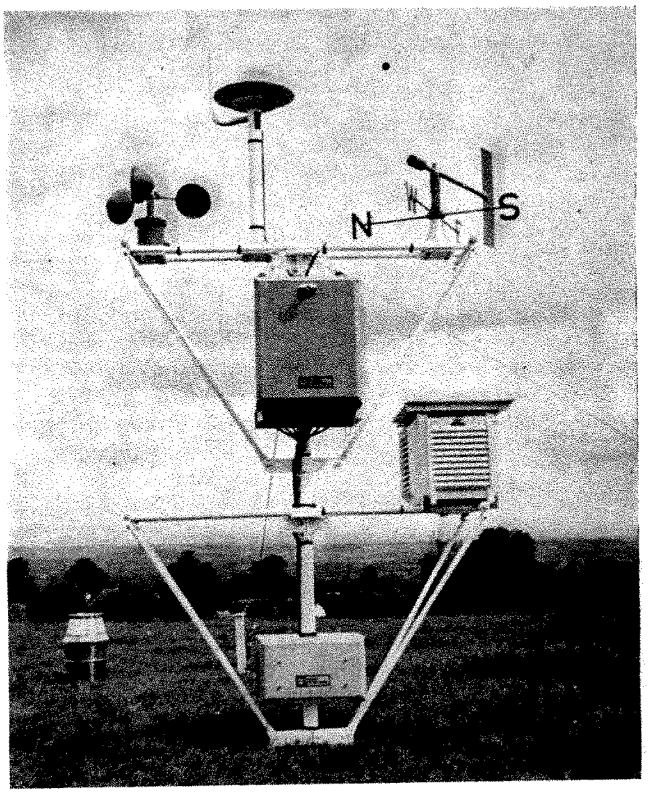
Finally, the report suggests that action should be taken to control the discharge of dust-laden air from asbestos factories and the dispersal of dust from waste dumps. It emphasizes, however, that the problem of mesothelioma in association with asbestos exposure should be kept in a proper perspective. Even though the incidence is increasing, the total number of cases of mesothelioma in Britain over several years is very small when compared with the annual total of deaths from cancers of the trachea, bronchus and lung.

Recording Weather

An automatic weather recording station which can operate unmanned for at least three months has been produced by the Plessey Company Ltd. This station, which can make and record more than 82,500 measurements in a three month period, is available from the Marine Systems Division of the Plessey Electronics Group at Ilford. The value of automatic weather stations was recognized by a recent report from the World Meteorological Organization (*Nature*, **215**, 1324; 1967). They are important because modern developments in weather forecasting require information about climate from all over the world—sometimes from uninhabited areas—and it is becoming increasingly hard to persuade amateur meteorologists to provide accurate data day by day. Professionals cost money, and so there should be a real market for automatic stations which can do the job reliably for long periods without attention.

The Plessey station is virtually self-contained and can monitor parameters such as rainfall, humidity, wind speed and direction, air, soil and water temperatures, barometric pressure, *p*H, solar radiation and water level and flow. The basic design was evolved in co-operation with the British Water Resources Board, the Meteorological Office and the National Physical Laboratory. By adding various instruments to the basic design, it has been possible to produce a family of stations including hydrometeorological, climatological, water level, water quality and recording rainfall stations. Each can be arranged for automatic operation, and the recorded data can be sent by telemetry to a control centre on demand.

Each station is supplied as a complete system with sensors, recorder, power supply, 'Stevenson' screens and a stayed aluminium mast which supports the sensors. The memory of the station samples up to eight sensors in turn, recording their outputs in ten-bit binary code on standard quarter-inch magnetic tape. It samples at intervals of 5, 10, 20, 30 or 60 minutes and is accurate to within 0·1 per cent.



Discomforts of Space

by Angela Croome

The next moves in manned spaceflight may be uncertain, but in both the United States and the USSR, background experiments for the longer flights of the future are going ahead. This month the McDonnell Douglas Corporation of California, contractors to the Office of Advanced Research and Technology of NASA (National Aeronautics and Space Administration), is to start on a two-month-long test of a closed system space chamber. The Soviet Union has recently completed a 70-day confinement experiment involving three men. American and Soviet trials have relevance both for survival in space and for the operation of manned submersibles under the sea.

In the case of the American closed life-support trial, four college students of the University of the City of Los Angeles are acting as experimental subjects. For a period of 60 days, they will exist on reclaimed water and oxygen from their own metabolic wastes. The test is believed to be the longest so far attempted under flight conditions using a closed water–oxygen loop. The closed water system consists of an evaporation unit, a charcoal filter and a condenser that reclaims moisture directly from the crew and from the air in the cabin. Oxygen will be reclaimed through a process of mixing hydrogen and carbon dioxide and then converting them to water and methane gas. The oxygen is recovered from the water by electrolysis and the methane gas is expelled. Atmospheric pressure within the cabin will be at 7 p.s.i. (half that at sea-level) and will consist of 3·1 p.s.i. oxygen and 3·9 p.s.i./nitrogen. The simulation of space conditions will not, of course, be complete, for the trial will take place on the ground where both men and system will operate under normal gravity.

The Soviet experiment has already taken place and lasted the full period of 70 days during which a medical doctor, an engineer and a journalist remained shut up together under cramped and uncomfortable conditions. The exact dimensions of the isolation chamber are not given, but it is described as small. All three subjects were thoroughly instrumented for the measurement of their physical condition during the test. Their regime was to fulfil a daily routine of work, eating, sleep and medical examination up till about the halfway stage when they switched to a "free" routine, doing as they pleased. The journalist of the group recorded reactions in his log at the end of the first three weeks: "Watch-keeping, dinner, medical examination, sleep—our life has acquired a feverish though monotonous rhythm. There is almost no free time left. But we are already beginning to feel exhausted. Stanislav [the doctor] is getting thinner, there is a stubble of beard on his cheeks and dark rings under his eyes. Leonard's eyes have become red and anxious. I cannot escape the feeling that some pungent fog is creeping into our tiny room. While gradually poisoning our brains, it makes us more intolerant towards one another".

But during the later period when there was no set routine, things seemed even worse. There was no longer a work schedule, but the men could pass the time as they chose—playing chess, reading or presumably sleeping. (Food preparation did not amount to much of a task as their diet was a typical space diet of dehydrates, concentrates, and tinned foods.) Now, they reported, time passed more slowly and nervous tension increased. Sleep was troubled and they had hallucinations of sound. They dreamt of music, singing and the noise of aircraft. None the less, no member of the group "deviated from the programme or complained"—complaint presumably being defined as a request for release from the experiment. The experimenter in charge comments that the trial was above all a test of character and willpower, but much useful information was gleaned.

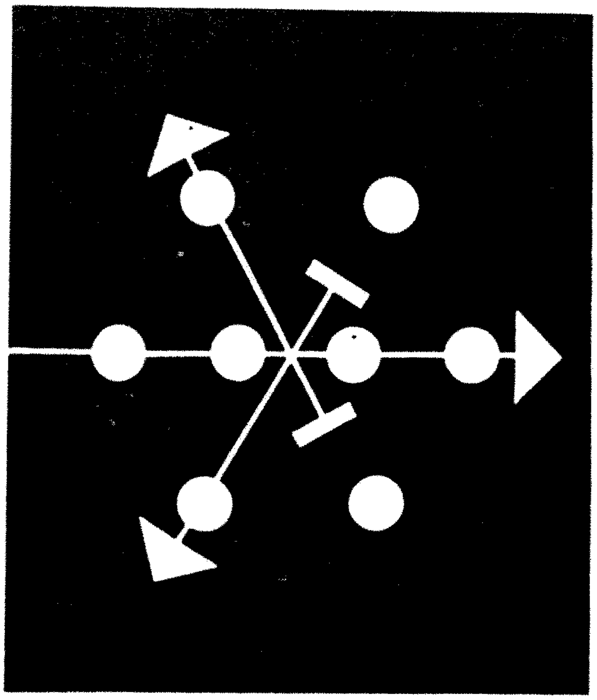
Mapping in Metric Units

One organization faced with a formidable task in changing to metric units is the Ordnance Survey. Among proposals which have so far been endorsed by the Joint Standing Committee in accomplishing this task are that heights will be shown in metres instead of feet on new and revised maps at 1 : 1,250 and 1 : 2,500 scales. Areas will be shown in hectares instead of acres on maps at 1 : 2,500 scale. Heights will be given in metres instead of feet on bench mark lists prepared from new levelling. Contours will be shown at a metric interval on new six-inch maps. Finally, the problems of changing the six-inch and one-inch maps to "rational" scales such as 1 : 10,000 and 1 : 50,000 will be reviewed. These proposals were circulated to 180 interested bodies, representing all classes of map users.

According to the annual report of the Survey for 1966–67 (HMSO, 7*s*. 6*d*.), in which these facts are published, the past year was marked by a change of ministry. In February the responsibility for the Ordnance Survey was passed from the War Office to the Minister of Housing and Local Government. Overall expenditure during the year was £5,715,000—about one-third of which was recovered by revenue from sales of maps and from royalties. On the whole, however, there was a falling off in demand for maps, which, the report suggests, is mainly due to the deferment of investment in development schemes in many parts of the country as a result of the Government's economic measures, together with an increase in the price of maps at certain scales. On March 31, the total number of staff was 4,090 non-industrial and 552 industrial compared with 4,008 and 540 a year earlier—a vigorous recruiting programme bringing in some 480 new staff.

Survey of the principal town areas on the scale of 1 : 1,250 is said in the report to be nearing completion and revision of the old 1 : 2,500 plans covering minor towns and rural areas has been speeded up, largely through the increased use of aerial photographs. Instead of the five-year re-levelling programme which was originally aimed at, subsidence areas will be levelled on a twenty-year cycle as in normal areas.

New Physics Symbol



The Institute of Physics and the Physical Society hopes that this symbol, when correctly placed on a red ground, will soon become familiar to anyone who has any acquaintance with physics. The symbol has been designed to accompany all kinds of information produced in connexion with the four-day Physics Exhibition opening at the Alexandra Palace on March 11. It is based on the weight diagram for the irreducible representation D^8 (1,1) of the $SU(3)$ symmetry which has been successful in bringing order to the classification of sub-atomic particles. Mr D. Walter, who is organizing the exhibition, first thought of basing the symbol on $SU(3)$ symmetry and, after advice from Imperial College, the final representation was drawn by Mr M. R. Preston of the Science Museum.

Letter to an Imaginary Soviet Scientist

The problems of cultural relations between countries which speak different languages are necessarily formidable, but the following letter suggests that these problems may sometimes be needlessly complicated.

Dear colleague,

The news of your election to the Soviet Academy has just reached us here, and I hasten to add my congratulations to those of your other friends and admirers. It does not seem fifteen years since we began to notice your name as the author of a series of brilliant contributions to our subject, and wondered whether you were as clever in conversation as you seemed in print. Nor does it seem as long as seven years since we actually met, and I learnt to value your cheerful, charming and provocative companionship. You deserve your honour, my dear friend, not only for your scientific work but for these human qualities which we have all appreciated on those few occasions when we have been able to have you with us in person.

Now that you have risen to this august rank you will, of course, have heavier administrative responsibilities—but you will also be able to play a larger part in the general direction of science in your country. Knowing you as I do, I can only feel that this will be beneficial both to the Soviet Union and to our subject throughout the world. The combination, within your person, of intellectual power and human judgment fits you almost uniquely for such a role.

Perhaps, therefore, you will excuse me, even on this especially happy occasion, if I mention something that has been worrying me from time to time and that has cast some small shadows over our friendship. It is not a matter that should stand between us personally—but I hope that you may exert your new-found authority to do something about it.

I allude to the extraordinary deficiencies, amounting sometimes to downright discourtesy, that hinder written communications and practical arrangements between Soviet scientists and ourselves. You must, I am sure, know the sort of thing I mean.

For example, a mutual friend arranged a conference here last December. Knowing the problems of "getting any Russians", he set to work in good time—or so he thought. In January he wrote to his opposite number in Moscow, an Academician, inviting him to come as a guest speaker. He also asked for the names of other good Russian scientists as possible invited speakers and participants. To this letter he received no answer. At the end of March, having nearly finalized the programme of review lectures, he wrote again to the Academician. Still no answer.

At this stage, he would have been justified in dropping all Russian names from the programme. However, being experienced in such business and genuinely wishing to hear at first hand about the work of the Moscow Institute, he wrote directly to the Presidium of the Academy and to the Ministry of Education, officially inviting six leading Russian scholars by name. This letter, sent in May, was answered in October, as follows "Dear Professor X, the Soviet delegation to your conference will consist of Y and Z. Please make arrangements for them to receive visas to enter your country."

Unfortunately, the two names mentioned in this brief and uncivil communication were not among those asked for. Indeed they were practically unknown to our friend, who could only assume that they were junior workers who had not yet risen to international prominence. He wrote back asking for more information, pointing out that he would not now be able to include these names in the official programme as invited speakers, but would welcome them nevertheless. He also set in motion the Foreign Office machinery for granting visas.

Again nothing seemed to happen until three days before the start of the conference, when a cable (in Russian) demanded accommodation for eight Russian scientists, including now the Academician himself. With tremendous energy, the organizing secretary wheedled six more rooms out of the local hotels, aroused the Foreign Office to action, and rearranged the programme. He even set graduate students awaiting at the airport to guide the party. But nobody came.

Finally, in the last two days of the meeting three Russians appeared, unannounced. One of them did not seem very familiar with the actual subject, but they all insisted on reading out their unscheduled communications. In the end, beer and vodka in the local pub resolved many inhibitions, and we soon became good friends. They were, indeed, full of apologies for any slight difficulty that may have been caused by the inefficiency of their bureaucracy—and once again we forgave them because, poor souls, it was not their fault that we had been put to so much trouble.

What puzzles me about such buffoonery (believe me, I do not exaggerate the sort of thing that often happens) is that it benefits nobody. If attendance at scientific conferences is valuable, then surely the most suitable Russian participants should have been chosen, by experts such as the Academician, and efficient arrangements made for their travel. Much expense and effort seems to have been wasted. And the international standing of Soviet science was not enhanced.

Well, of course, we too have our difficulties sometimes in persuading financial committees to make grants for travel to conferences, and in rearranging our university duties so as to get leave of absence: sometimes even nine months is an insufficient gestation period for such important administrative decisions. But at least the advice of expert scientists is followed. I know that it would not be fair to blame your Academician personally for this particular fiasco; but I cannot think of anyone else with the knowledge needed to take such decisions and to bear the responsibility for their success.

You must yourself have suffered through similar events, and do not need to be told by me that they are harmful to the Soviet Union and its scientific development. I can only say, as an outsider, that they really cause us a great deal of trouble, to the extent that many of us, in organizing international scientific meetings, may begin to feel that it is not worth the effort to try to get Russian participation. There is a limit, in terms of time and worry, to the price that we are prepared to pay for this commodity, however valuable it may be to us. I hope therefore that, in your new rank, you will press, through the Academy and other organs of the Soviet scientific community, for a great improvement in the practical management of all such matters.

Yet there is a more subtle aspect of relations between Russian and "western" scientists that cannot be improved by mere administrative reorganization. I have mentioned letters that were not answered, nay, not even acknowledged. Friends have told me of the rebuffs they have received in planning a visit to the Soviet Union. For example, polite requests to talk to such and such a scientist have been fobbed off or simply ignored. We all know of the custom of translating scholarly works into Russian, without consulting the author, despite the advantages that may be gained from his advice concerning printing errors. Are these and other incivilities always to be forgiven ?

Can it be that you and your colleagues are simply unfamiliar with our ways, just as we must be with yours ? Consider, for example, the general tone in which correspondence is conducted between established scientists in different countries. It is hard to characterize this tone specifically, but it is always courteous and friendly, whether formal or informal. From an unknown German or Italian, a letter might be written in the old-fashioned style of conventional respect; from an American friend it might be all on first-name terms, with chat about each other's family. In every case, the letter would be addressed as from person to person, without passing through the bureaux of organizations, academies, universities, or other institutions. The courtesies would be those normal between independent individuals, asking perhaps for advice or assistance, regretting in return the inability to give such help, conveying opinions or information, making practical arrangements, etc.

The point is that, however much we may be in fact employees of universities, government laboratories or industrial corporations, we still like to regard ourselves as persons of independent standing, capable of deciding for ourselves on all matters associated with our professional activities—what subjects to work on, when and what to publish, whom to meet and talk to, where to go for conferences and advanced instruction. I do not say that we are in fact quite as free as we like in all such questions; we must, indeed, perform our university duties and otherwise satisfy our directors of research and governing boards—but we are not mere functionaries. To fail to answer a letter from one such scholar to another is therefore something worse than administrative inefficiency—it is a personal insult. To act as if one scientist is interchangeable with another as the speaker in a conference is an attack on the personal standing of each one of us. To give meaning to our work, we need to preserve the illusion that we are contributing individually to the growth of knowledge and that each one of us deserves to be treated as the independent proprietor and cultivator of his own little cabbage patch in the land of learning.

You yourself, I know, have never offended in this way; all I ask now is that you try to explain to your colleagues the importance of such apparently small issues. Our mutual good relations depend on an implicit respect for each other's position by an explicit regard for his social conventions. An improvement at this level would be of far greater benefit than any number of cultural exchange agreements between our respective governments.

These benefits would not be merely a vague increase in "international understanding". It is now clearly established, by those who have studied the sociology of science, that the informal channels of communication between scholars are quite as important as the official organs of scientific publication. Information about new discoveries and new techniques diffuses very rapidly through our scholarly communities by means of letters, visits and personal contacts at conferences. To be cut off from such contacts is one of the main complaints of scientists in small countries, far from Europe and North America; it hampers their research at every level, seeming to make it always a little out of date. If we could unblock these channels between the Soviet scientific community and our own, then we should both benefit greatly; we should not have to learn, by painful experience, some of the things that you already know; your research would always start from the best possible basis of knowledge, including some of those subtle ideas that we have already conceived. I cannot emphasize this point too strongly to you, to your professional Russian colleagues, and to all those who have anything to do with the scientific development of your country. I know very well that there are obstacles to the opening of all doors between your scholarly community and our own; at least a general amelioration of the level of civility in personal communications would unlatch a few windows between us.

You will, I trust, forgive me for having spoken so bluntly. I have not the least complaint against the way that you have treated me over these many years. The role of the "candid friend" is dangerous and foolish in personal relations. But this is not, in the end, a question of the relationship between private individuals; it concerns whole communities, great nations and our common dedication to the pursuit of knowledge; to fail to speak our minds honestly is to betray our social responsibilities. Perhaps we too are unwittingly offending you by our behaviour; give us the opportunity to show our emotional maturity by accepting your criticism in a humble spirit.

Meanwhile, dear friend, we must make the best of our little lives within our chosen spheres. Once more let me congratulate you on the recognition that has crowned those past years of toil and effort and wish you many years of further success, the delights of yet more discoveries, and the fruits of wisdom and understanding.

Arrivederci : to the time when we meet again.

Yours ever,

JOHN ZIMAN

H. H. Wills Physics Laboratory,
University of Bristol.

NEWS AND VIEWS

What is to Happen about Fusion?

THESE are dog days for those who wish to see a rapid development of the kinds of devices which may in due course lead to the development of fusion reactors capable of extracting power from the thermonuclear fusion of light elements. In Britain, the laboratory at Culham will be running on progressively tighter budgets in the five years ahead, for the rate of expenditure is to be reduced at 20 per cent a year for each of the next five years. In the United States there has been a modest increase of expenditure in recent months, but the scale on which large experiments are undertaken in the United States will remain comparatively modest. Gone, for the time being at least, are the days when men working with machines such as that once known as NRX (at Los Alamos) were inclined to think that they would soon be able to accomplish the tricks which had earlier eluded the British machine called ZETA. Instead, everybody is taking a sober view of the problems that will have to be solved before thermonuclear power can become a reality. Plasma physics is the watchword, not fusion research. So long as this is properly appreciated, however, it is valuable to be reminded, now and again, of the potential benefits there would be if fusion reactors ever became a practical proposition.

At least the uncertainty over the scale of support for fusion does not seem to have demolished the confidence of its supporters. Workers at Culham and elsewhere are going ahead with research and even with engineering designs for full scale power reactors. Last month, Mr R. Carruthers from Culham described just such a study for a 2,100 MW (e) fusion power station which would, he said, cost substantially less than the advanced gas cooled reactors being built at Dungeness, and which would generate electricity 10 per cent more cheaply than a fast breeder reactor. Fuel costs would be negligible and there would be no problem of disposal of radioactive waste.

Although some may feel that it is optimistic indeed to design a reactor before the fundamental problems of plasma containment have been solved, there had until last week been little argument about the question of waste. On more than one occasion, indeed, supporters of fusion as a source of power have compared the messy results of fission reactors with the clean, waste-free designs for fusion reactors. The announcement last week by the European Nuclear Energy Agency that it has started to dump radioactive waste in the eastern Atlantic as a collaborative project involving five European countries brought home just how large the problems of disposal will have become by the end of the century. But now, in a paper in *Science* (**159**, 83; 1968) Dr Frank L. Parker of the Health Physics Division at the Oak Ridge National Laboratory in the United States has suggested that fusion reactors would indeed be a source of harmful waste, in the form of tritium lost by the reactor vessel. Dr Parker considers a reactor in which deuterium reacts with tritium —the same design as that described by Mr Carruthers —and quotes results obtained by Professor D. J. Rose at Massachusetts Institute of Technology. These figures, he says, show that for every tritium atom burned 1·15 atoms have to be produced. This means that 15 per cent of the tritium produced is lost, and this would be equivalent to $1\cdot1 \times 10^6$ curies of radioactivity a day for a 1,000 MW (e) station.

This calculation seems a little wild, and Mr Carruthers is undeterred by it. The fact that tritium is lost does not mean that it is all lost to the atmosphere. On the contrary, in a working reactor, most of the tritium would be recirculated. Some would be absorbed into the material of the reactor and a small but not negligible amount would be lost by decay. Although it would be important to ensure that tritium leakage was minimized, he says, the problem would not be as great as Dr Parker feared.

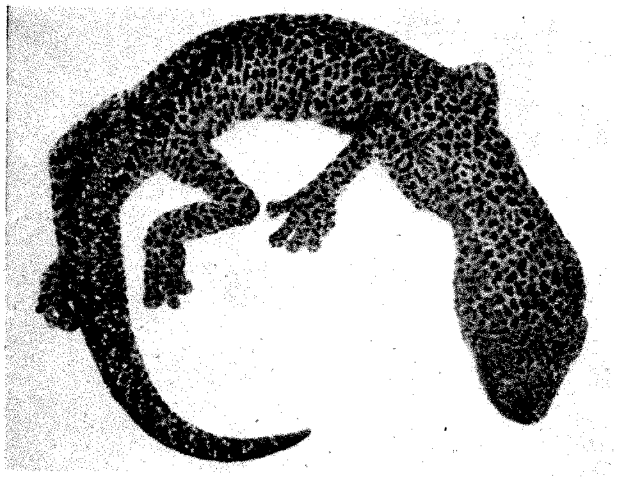
An Account of Geckos

GEKKONID lizards are perhaps best known for their vocalization and for their ability to climb smooth vertical surfaces by means of dilated areas—suction pads—on the ends of their digits. There is, however, much more to their biology than this. It is perhaps not so well known that a few forms have extensive skin folds on their bodies and tails which, when extended, enable the animal to glide from tree to tree. Some species are even known to excavate their own tunnels. The family indeed shows a wide range of structural and biological diversity, and it has adapted to most environmental extremes. An authoritative account of the biology of the family has been written by A. G. Kluge (*Bull. Amer. Mus. Nat. Hist.*, **135**, 1–60; 1967). In this paper, Dr Kluge also discusses the taxonomy and evolution of gekkonid lizards, and he proposes a new sub-familial classification which differs in some features from that suggested earlier by Underwood. In a more recent publication, with more specific appeal, Kluge now deals with the systematics, phylogeny and zoogeography of the genus *Diplodactylus* Gray (*Aust. J. Zool.*, **15**, 1007–1108; 1967).

The Gekkonidae are found on all the main land masses between the latitudes 50° N. and 50° S. The genera number 82, and some 650 species have been identified. Adults vary in total length from less than 40 mm to more than 350 mm. The digits are long and slender, angulate or straight to very dilated. Some species have webbed hands and feet, and there are some with sharp retractile claws. The "suction pads" consist of divided or undivided lamellae, each of which bears numerous microscopic, hook-like projections that appear to facilitate movement in trees.

Maderson (see *Nature*, **203**, 780–781; 1964) has suggested that this climbing mechanism is dependent on an electrostatic charge rather than on adhesion, but experimental work to support or reject the theory does not appear to have been carried out. Gekkonid tails, which are almost always autotomic (self-amputating), vary in size from one species to another; in some forms the tail becomes very swollen with fatty tissue, apparently serving as a food reservoir. The eyes of gekkonids must be one of their most striking features. The margins of the iris are very mobile and it seems as if this mobility has enabled members of the family to adapt to a wide range of light intensities. In most forms, the eyes are protected by a spectacle (brille) instead of movable eyelids. Apparently it is common for geckos to lick their spectacle with their tongues and so clean it in the absence of movable eyelids which normally perform this function.

Most gekkonids are nocturnal and arboreal in their habits, although there are exceptions; a few are cavernicolous, and some species actively feed and bask in the direct sunlight. They are primarily insect-eating, but the larger species are known to eat other lizards and even small birds and mammals.



Dorsal view of *Diplodactylus taenicauda* from Queensland. (Kluge, A. G., *Aust. J. Zool.*, **15**, 1967.)

Kluge reviews the fossil history of the family, and suggests an Upper Jurassic–Lower Cretaceous origin; he also suggests that the limbless lizards of the family Pygopodidae have evolved directly from the Gekkonidae. He does not agree with Underwood's classification of gekkonids which is based on the shape of the pupil; Kluge considers this classification unnatural because of the variability of diagnostic characters. Instead, he uses eighteen characters to group the 82 genera into four sub-families of equal rank: the Eublepharinae, Sphaerodactylinae, Diplodactylinae, and the Gekkoninae. The number of assemblages recognized and their names coincide with those of earlier studies. The difference lies in Kluge's definition of Eublepharinae and Sphaerodactylinae as sub-families. Underwood had Eublepharidae, Sphaerodactylinae and Gekkonidae as three families, with Gekkonidae subdivided into the sub-families Gekkoninae and Diplodactylinae. Kluge points out that although he has retained Gekkoninae and Diplodactylinae, their generic composition is very different from that in Underwood's groupings.

Kluge considers that not only do his four taxonomic groups agree with the morphological characters of gekkonids, but that they are consistent with present thought on zoogeography. It appears that south-east Asia was their place of origin. Kluge comments on the early evolution and dispersion of the different sub-families; the Diplodactylinae are thought to have dispersed from Asia towards Australia by way of the Indo-Australian Archipelago. It is postulated that the sub-family reached Australia by Palaeocene–Eocene times. Today the Diplodactylinae are restricted to the Australian region (Australia (excluding Tasmania), New Caledonia, Loyalty Islands and New Zealand). Kluge gives distribution maps for all the sub-families.

Molecules Constrained

from our Thermodynamics Correspondent

THE second instalment has now appeared in the *Proceedings of the Physical Society* (*Journal of Physics A*, **1**, 15; 1968) of the treatment by Professor S. F. Edwards of the consequences for statistical mechanics of the imposition of topological restraints on long-chain molecules. The long-term objective is to construct a theoretical framework for the statistical mechanics of assemblages of long-chain molecules. The first instalment of Professor Edwards's analysis (*Proc. Phys. Soc.*, **91**, 513; 1967) was largely confined to two-dimensional problems, where the imposition of restraints can be represented by the appearance within the array of molecules of an impenetrable point, the effect of which may be likened to the threading of a needle through a ball of knitting wool. The immediate result is to sort the molecules into various classes on the basis of their topological relationship with the constraint. Some of them, for example, will pass on one side of the constraint and some on the other side, and there is an infinite set of categories for molecules which are looped around the constraining point for varying numbers of times. The essence of the problem in two dimensions is to calculate the probability that a flexible molecule of given length will fall into each of the various categories defined in this way. In practice, this is a random walk problem with restraints. It is no surprise that when the calculation has been carried out, the free energy of the assemblage turns out to be an additive function of the properties of the molecules in the several categories. One cheerful feature of the calculations is that the free energy comes out as an explicit function of the geometrical co-ordinates of the restraint, which means that elastic constants and the like can be calculated directly.

The three-dimensional problem is considerably more difficult, and in his latest article on the subject Professor Edwards has done little more than show how to sort long flexible molecules into categories on the basis of calculable topological invariants. The point restraints of the two-dimensional problem must be replaced by entanglements with other molecules, and for each degree of complexity of entanglement there is a separate invariant to be calculated. Professor

Edwards has calculated the first two of these, corresponding to the entanglement of molecules in twos and threes respectively Experience elsewhere, as in the evaluation of integrals representing multiple interactions in liquids, for example, would suggest that the value of calculating many more complicated members in this series will be limited More immediately, however, it is interesting that the expressions for the probability of molecular configurations defined by definite values of the invariant integrals turn out to be identical with the formalism of the quantum field theory of charged scalar mesons—problems of renormalization included One obvious possibility is that the construction of a series of Feynmann graphs of increasing complexity will be a convenient intuitive means of classifying molecular entanglements of increasing complexity Given the extra complexity of real assemblages of molecules, however, the chances are that the new theoretical calculation will help with the description of the properties of real assemblages of long molecules—pieces of rubber, for example—intuitively rather than by exact calculation It is therefore important that Professor Edwards has already described how existing theories of rubber-like materials should be modified to take account of molecular entanglements (*Proc Phys Soc*, **92**, 9, 1967)

New Plants from the Past

by Mary Lindley

DEVONIAN plants, two of them newly discovered, were the subject of a symposium held by the Palaeobotany Group of the Linnean Society on January 2

As Professor T M Harris said in his introduction, widespread botanical interest was only focused on the Devonian in 1917 when the famous deposit was found in the village of Rhynie in Aberdeenshire, when Kidston and Lang described the three vascular genera *Rhynia*, *Horneophyton* and *Asteroxylon* with their erect dichotomously branched stems, covered with leaves in the case of *Asteroxylon* and naked in the other two genera In the Rhynie Chert, Kidston and Lang also found specimens which they supposed to be the fertile part of *Asteroxylon mackiei*, the type species of the genus, but in 1964 Dr A G Lyon—a botanist who also happens to own the Rhynie Chert—described lateral sporangia of *A mackiei*, suggesting that the fertile parts found by Kidston and Lang were a separate plant, to be called *Nothia aphylla* At the meeting Dr W S Lacey described some work by a former student of his, Dr W El-Saadawy, who has examined new specimens and established that *Nothia aphylla* is a separate species with a slender dichotomously branching stem and terminal sporangia

Dr Lyon himself reported a new plant from the Rhynie Chert, the first for almost fifty years Two years ago he found some very localized remains which, by virtue of their xylem, could not be pieces of arachnid leg They turned out to be sections of a stem with epidermal hairs—unicellular outgrowths from epidermal cells—which clearly distinguish this plant from the others of the Rhynie Chert The stem has xylem—the conducting elements are tracheids with what appears to be annular thickening—surrounded by large phloem like cells and then cortex There were also many sporangia associated with these remains, but their mode of arrangement is uncertain An unusual feature is that the vascular tissue appears to pass into the sporangium and then fan out. Dr Lyon thinks that this plant is different enough to be put in a genus of its own, but he would not reveal the name that he is proposing for it, it remains the "hairy plant"

Another new plant was described by Mrs Dianne Edwards when she discussed the Lower Devonian genus *Cooksonia*, one of the earliest plants to be successful on land This genus, with terminal sporangia borne on a naked dichotomously branching stem, has been described from sedimentary rocks in England and also Czechoslovakia and Russia There is a great deal of variation within populations, and the relative maturity of specimens may add to the difficulty of the taxonomist, whose specimens may anyway be very poor Mrs Edwards was very dubious about the Russian species, *C rusanovii*, which is based on one very bad specimen She was also suspicious of the two species of *Cooksonia* described by Lang, who named the genus in 1937, and thinks that the two may grade into each other Mrs Edwards has also found better specimens of *C downtonensis* and thinks that this should perhaps be in a genus separate from Lang's *Cooksonia* Her own species of *Cooksonia* was found in Scotland, and is very like Lang's species In this case, however, the sporangia have thickening around them and each one has a definite and distinctive base Like Dr Lyon, Mrs Edwards would not divulge the name she has given to her new plant

A new find which has proved more mysterious was described by Mrs Margaret Mortimer She and Dr W G Chaloner have been studying specimens of a cellular membrane which first turned up in lower Devonian rocks in South Wales, and later in boreholes in Cambridgeshire and the Sahara The specimen shows a network of irregular cells, probably in more than one layer, containing regular circular pores This is quite unlike the cuticle of any Devonian vascular plant, and in this case there is no evidence of stomata On the assumption that it is not an animal membrane—it has not been recognized as belonging to any animal—the membrane compares best with the cuticle of some non-vascular Devonian plants, and best of all with *Spongiophyton* Although the specimens in question have nothing to compare with the larger pores in the cuticle of *Spongiophyton*, Mrs Mortimer and Dr Chaloner are inclined to think that this is the correct identification It clearly illustrates the sort of detective work in which the palaeobotanist has to indulge when identifying his specimens

Enzymes made Insoluble

from a Correspondent

THE attendance of 200 people at the Biochemical Society's colloquium on enzymes attached to solid matrices, held at the Medical College of St Bartholomew's Hospital last Friday, was no mean achievement for the organizers when it is considered that only a few years ago the subject was often regarded as obscure

Enzyme molecules have been made insoluble in four ways, by adsorption (ionic or otherwise), by immobilization in a gel, by cross-linking either immediately or after absorption on to a solid matrix and by covalently coupling them to a suitable insoluble polymer. Of these methods, the first is usually considered to be inadequate, although methods successfully employing such preparations have been reported and "irreversible" adsorption has been described. Cross-linking was not considered in detail at the meeting, but physical entrapment in a matrix was considered a serious rival of covalent attachment, on which most of the work has been carried out. It was suggested that if a gel were used in the preparation of the enzyme, for example, in electrophoresis, then the enzyme thus trapped could be treated as an "insolubilized" preparation. Some doubts were expressed about the stability of trapped enzymes. In general a covalently linked enzyme is more stable than the corresponding free enzyme. Inactivation by extremes of pH or temperature, oxidation or bacterial attack is reduced. There was little information about the stability of trapped enzymes except that in at least one case it was reported that there was no protection against oxidative inactivation.

Covalent attachment of enzymes was considered in some detail. About a dozen hydrolytic enzymes and half a dozen enzymes of other categories have been made insoluble by these methods. The amount of enzyme activity remaining after coupling varies from 30 per cent to 50 per cent and, in one or two cases, to 100 per cent of the free-solution activity. In some cases the supporting polymer may contain more than its own weight of enzyme.

Insoluble enzymes can be used as models for *in vivo* enzyme systems and as catalysts for analytical and preparative procedures. The possibility of using enzymes made insoluble also to reproduce the transport phenomena associated with natural membranes was discussed at the meeting, and the preparation of a system with potato-apyrase was reported. This work, however, is still in the early stages.

No striking process was described in the industrial and analytical uses of insoluble enzymes. Attention was drawn to the importance of diffusion as a limiting factor on the activity of enzyme preparations which have been made insoluble. Experiments were described in which the effective rate of catalysis by such a preparation can be doubled by increasing the stirring speed in the reaction vessel. Reasons were given for believing that a packed bed would be preferable to a continuous feed stirred tank when employing these catalysts. The preparation and use of enzymes attached to "porous sheets"—filter paper and filter cloth—were reported, as was the use of several such sheets in series.

Industrial Microbiology

THE Microbiology Group of the Society of Chemical Industry celebrated the New Year with a meeting on January 2 about the problems of maintaining pure cultures in industrial fermentations. This is an important economic question. Mr B. G. W. Hodds of Glaxo Ltd, Ulverston, provided a lucid introduction to the subject by describing how an industrial fermentation can frequently be ruined as a result of contamination by bacteria, yeasts, moulds, bacteriophages and actinophages. Sometimes the production of a micro-organism or one of its metabolites can be completely swamped by an intruder. In the production of streptomycin, for example, contamination by actinophage can cause complete lysis of the culture, which is why prudence suggests the addition of citrates to sequester calcium and magnesium ions necessary for the development of the actinophage. But how to know when a culture is contaminated? Mr Hodds emphasized the problem of distinguishing microscopically between contamination and abnormal development of the cultured organism. In brewing, to be sure, the low pH of fermentations and the antibacterial action of hops serve as a means of protection. Fermentations intended for the production of antibiotics also have a degree of self-protection except when contaminating micro-organisms are resistant to them. Bad luck or bad management here can mean the loss of a whole vat, the contents of which might be worth £10,000. How then to avoid contamination? This, said Mr Hodds, is not just microbiology but management. He pointed out that the training of recruits and the clear supervision of foremen are important factors in reducing the chances of contamination. Speedy identification and elimination are important if the contamination of a whole plant is to be avoided.

Much can also be done by good design, and Mr J. F. Thorley of Dista Products, Speke—the star turn at the symposium—urged that simplicity of design helps to keep out contamination. The more numerous the connexions to a vessel, the more difficult it is to sterilize. Smooth polished surfaces of stainless steel are a great help. So too is continuous welding.

But what is the cost of freedom from contamination? G. D. Wilkin of the Boots Pure Drug Company, Nottingham, said that any plant could be run under sterile conditions at a price. The more valuable the product and the larger the plant, the more it is worth paying for security.

The risk of contamination is most feared, however, in the production of vaccines, either viral or bacterial. Dr J. R. Hepple of Glaxo Laboratories Ltd explained how even a simple antigenic variation of an organism is enough to render a batch of vaccine useless. This means that the micro-organism must be kept in the pure form and in the correct physiological state, both in the seed and the batch cultures. But it is also necessary to ensure that the tissue on which a virus is being cultivated should be free from other viruses and bacteria.

More Light on Ribonuclease

from our Molecular Biology Correspondent

PANCREATIC ribonuclease is the enzyme about which most is known, in terms of both structure and function. The working out of the three-dimensional structure, supported by the accumulated mass of protein chemistry, is now beginning to pay impressive dividends: the current literature offers some especially interesting examples.

A second pancreatic ribonuclease—from the rat—has been fully sequenced by Beintema and Gruber (*Biochim. Biophys. Acta*, **147**, 612, 1967), and it is remarkable to discover that differences from the bovine enzyme occur in no fewer than one-third of the positions in the chain. Frequently there are substitutions of polar (for non-polar) residues, but it appears that in all cases the replacements fit without strain into the model obtained for bovine ribonuclease by Richards and his associates; this leads one to expect that the structure will be essentially the same, despite the large differences in sequence. The residues known to be parts of the active centre remain in place, and the overall charge is also essentially unchanged. Most of the substitutions are in fact at the surface of the molecule: in the closely packed hydrophobic interior, the steric restrictions are exacting. Among the substitutions are three new proline residues, none happily in α-helical sections of the chain. A partial sequence of horse pancreatic ribonuclease is also presented, and shows considerable differences from the other two.

The rat enzyme has three extra residues at the *N*-terminal end, and the *S*-peptide region is therefore enlarged to 23, as well as differing in no fewer than 10 of the other 20 residues from bovine *S*-peptide. (The *S*-peptide, it will be recalled, is the terminal segment which can be removed after proteolytic fission of one bond, with complete loss of activity: if it is returned to the truncated enzyme, it attaches non-covalently, with full restoration of activity.) This is interesting, in view of recent work on synthesis of *S*-peptide analogues. It is known that six residues can be excised from the *S*-peptide without detriment to its function. Finn and Hofmann (*J. Amer. Chem. Soc.*, **89**, 5298; 1967) have now shown that elimination of his-12—part of the active centre—from the *S*-peptide leads to loss of reactivity, but hardly at all of affinity for the residual *S*-protein. The sites which are vital for attachment to *S*-protein, rather than activity, are glu-2, asp-14 and met-13, and these may not be tampered with. All these, as expected, are unchanged in the rat enzyme, whereas all six inessential residues (15–20) are changed. Scoffone *et al.* (*ibid.*, 5450) have also synthesized *S*-peptide analogues: arg-10 has been replaced by ornithine, and phe-8 by tyrosine, isoleucine or alanine. In the last two cases binding is diminished, but tyrosine replaces phenylalanine with hardly any disadvantage. This is curious, for phe-8 is an internal residue, so the usual steric exclusivity is violated. Even in the other two cases, activity remains when a large excess of peptide is added to induce a measure of binding.

Yet another fascinating observation is that of Neumann *et al.* (*Europ. J. Biochem.*, **3**, 171; 1967), who have achieved partial reduction of pancreatic ribonuclease with a new reagent, phosphorothioate. In general, the four disulphide bonds are protected in the native state, but with this reagent two are cleaved in aqueous solution. The broken cystines have been identified by peptide mapping. As in one or two other cases recently reported, the partly cleaved ribonuclease retains its native conformation by all criteria. Thus it is immunologically identical with the native protein, and the three buried tyrosines remain non-titratable, and are exposed only on denaturation. In particular, the activity towards RNA is fully intact, and the activity towards cytidine cyclic phosphate is actually enhanced more than two-fold—it must be supposed by virtue of increased flexibility. The two surviving cystines are essentially "internal" residues. The susceptibility of the protein to attack by trypsin is much increased, which suggests that a general loosening of the structure can be tolerated, and that the steric limitations for activity are quite modest in large tracts of the sequence, as the wholesale substitutions in the rat enzyme also indicate.

Model Cell Membranes

from a Correspondent

Artificial cell membranes, less than 100 Å thick, can be prepared by allowing a film of lipid to form across a hole in a polythene cup separating two aqueous phases. Increasingly, these preparations are being used as model systems to test particular hypotheses in membrane transport. Thus, Tosteson and his colleagues (Andreoli *et al.*, *J. Gen. Physiol.*, **50**, 1729; 1967) have been trying for a number of years to define the molecular basis of the difference between the HK (high potassium) and LK (low potassium) strains of sheep, where potassium refers to the concentration of this ion in the red blood cells of these animals. Transport studies have shown that the two strains differ in the ionic permeabilities of their cell membranes; the HK sheep are sodium selective, and the LK sheep prefer potassium ions. In the present paper, the lipids have been isolated from the cell membranes, artificial membranes prepared from these lipids and the permeability of such membranes measured. It is disappointing that artificial membranes from the two strains of sheep differ in no significant way; the artificial membranes do not distinguish between sodium and potassium and are also more permeable to these ions than to chloride. In contrast, the intact cell, for both strains, has a chloride permeability some 10^6 times greater than that for cations. The difference between intact cells and model membranes seems to lie in the contribution of the membrane protein, and it is here that the gene distinguishing the HK and LK strains must act.

Another example of the impact of model membrane studies comes from Cass and Finkelstein (*J. Gen. Physiol.*, **50**, 1765; 1967), who have compared the water permeability of thin lipid films, when water movement occurs by diffusion (using isotopically labelled water) or by hydrodynamic flow (on setting up an osmotic gradient across the membrane). Studies of cell membranes have often shown that these two permeability coefficients differ. Because hydrodynamic flow across porous membranes, but not diffusion flow, is affected by the pore size, results such as these suggest that water moves through cell membranes along narrow channels. It was very surprising, therefore, that early studies on the artificial lipid membrane—presumably a continuous bilayer—showed a difference between the two permeability coefficients. Cass and Finkelstein now show that the early results were almost certainly caused by the presence of unstirred layers of water in the diffusion experiments and that for the lipid bilayers the diffusion and hydrodynamic permeabilities for water do not differ. Hence water movement most probably occurs after dissolution in the lipid. It is pertinent to recall, therefore, Dainty's suggestion that diffusion studies on intact cells may be in error because of the presence of unstirred layers. For the human erythrocyte, however, where the two permeability coefficients differ by a factor of 2·4, an elegant study (Sha'afi *et al.*, *J. Gen. Physiol.*, **50**, 1377; 1967) has shown that the unstirred layer is only 5·5μ thick, and that the effect of this layer is insignificant. Valuable as the studies on artificial lipid membranes may be, therefore, they strongly suggest that membrane proteins play at least as important a part as lipid in determining the permeability properties of cell membranes.

Reconstruction of Three Dimensional Structures from Electron Micrographs

by

D. J. DE ROSIER
A. KLUG
MRC Laboratory of Molecular Biology,
Hills Road, Cambridge

General principles are formulated for the objective reconstruction of a three dimensional object from a set of electron microscope images. These principles are applied to the calculation of a three dimensional density map of the tail of bacteriophage *T4*.

THE standard high resolution electron microscope has a depth of focus of several thousand Ångströms, making the image a two dimensional superposition of different levels in the three dimensional structure. The focus cannot be adjusted to different levels within the object, and so three dimensional structures are difficult to analyse. Stereo-electron micrographs do not overcome this difficulty satisfactorily, as will be shown.

Our method starts from the obvious premise that more than one view is generally needed to see an object in three dimensions. We determine first the number of views required for reconstructing an object to a given degree of resolution and find a systematic way of obtaining these views. The electron microscope images corresponding to these different views are then combined mathematically, by a procedure which is both quantitative and free from arbitrary assumptions, to give the three dimensional structure in a tangible and permanent form. The method is most powerful for objects containing symmetrically arranged subunits, for here a single image effectively contains many different views of the structure. The symmetry of such an object can be introduced into the process of reconstruction, allowing the three dimensional structure to be reconstructed from a single view, or a small number of views. In principle, however, the method is applicable to any kind of structure, including individual, unsymmetrical particles, or sections of biological specimens.

Summary of Procedure

Electron micrographs are selected in which the details of the structure show up best, as judged for example in the phage tail described later, by their optical diffraction patterns[1,2]. The optical density in each image is sampled at regular points on a grid by an automatic microdensitometer linked to a computer (unpublished work of U. W. Arndt, R. A. Crowther and J. F. W. Mallett), which converts the image into a set of numbers representing the density at each grid point. These numbers are now transformed by computation into a set of Fourier

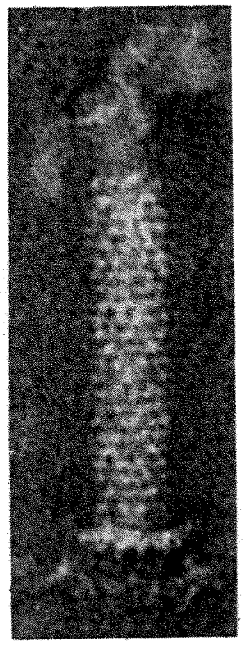


Fig. 1

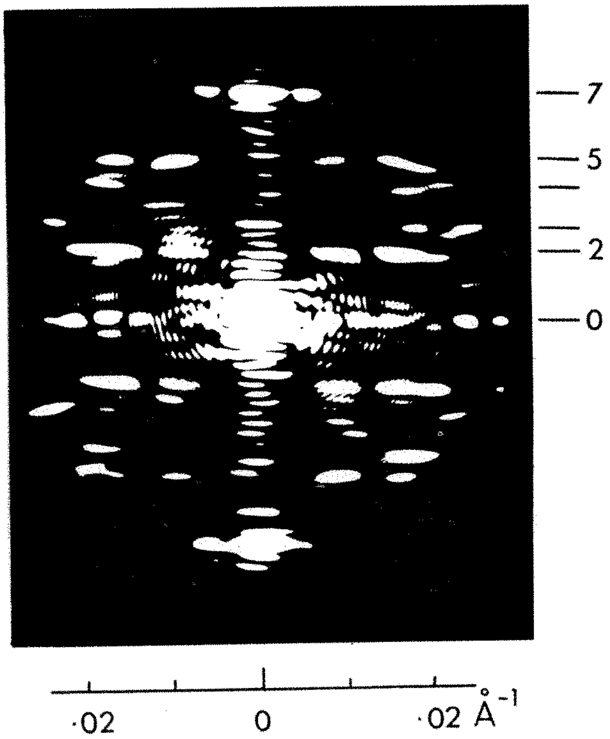

Fig. 2

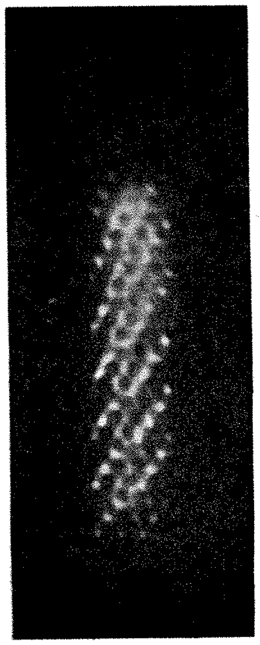

Fig. 3

Fig. 1. Electron micrograph of a tail of bacteriophage *T4*, negatively stained with uranyl formate. (× 500,000.)

Fig. 2. Optical diffraction pattern of the phage tail image in Fig. 1. Stronger exposures show that the order in the micrograph extends to spacings of about 25 Å. The strong meridional peak on the seventh layer line arises from the spacing of 38 Å between annuli. The layer lines are approximately equally spaced at the orders of an approximate repeat of 7 × 38 = 266 Å. The helical selection rule for the diffraction pattern is $l = 2n + 7m$, the only permitted values of n being those which are multiples of six.

Fig. 3. Optically filtered image of phage tail in Fig. 1, admitting only the diffracted rays corresponding to the far side of the particle. The dominant features are two distinct sets of oblique striations, which correspond to two distinct sets of helical lines running along two cylindrical surfaces of different diameter, and thus correspond to features at different depths in the particle.

amplitudes and phases*. A Fourier synthesis is then carried out which takes into account the symmetry of the object† and which builds up a three dimensional map of the structure. The density at each point on this map is made up by the summation of Fourier components contributed by all the different images of the object. This final step is similar to the method which is used by crystallographers for building up three dimensional maps of molecules from the amplitudes and phases of the X-rays diffracted by a crystal. The X-ray diffraction pattern lacks information about the phases, but these are readily calculated here from the density distribution in the original electron micrographs‡.

Application to the Tail of Bacteriophage *T4*

The tail of the *T*-even bacteriophages is made up of a core surrounded by a contractile sheath[8]. This contains protein subunits arranged in successive annuli which are rotated with respect to one another, so that the subunits also lie along oblique helical lines. On injection of the phage DNA into the host cell the sheath contracts, riding up the core. By comparing extended and contracted sheaths, we hope to discover the path of the contraction process.

Fig. 1 shows an electron micrograph of an extended phage tail which has been negatively stained. Its optical diffraction pattern, reproduced in Fig. 2, is essentially symmetrical about the meridian; because the tail is helical, this shows that the micrograph is made up by superposition from equally contributing substructures at the near and far sides of the particle[1]. The diffracted rays from the unwanted side of the particle can now be filtered out, and a good image of the other side obtained by optical recombination of the remaining diffracted rays[2]. Fig. 3 shows such an image from one side of the phage tail, but the picture is still complex, because it contains detail coming from different radii of the particle. This difficulty is overcome by our new reconstruction method which allows us to work in three dimensions and thus to separate the various radial contributions§.

Fig. 5 shows a model of the phage tail, consisting of the core together with its sheath, obtained by application of this method to the image in Fig. 1. It represents a Fourier synthesis of the particle at a resolution of 35 Å, in which the solid parts represent regions inaccessible to the negative stain. Comparison of such density maps from four different particles revealed only slight differences. The model contains two sets of black wires threaded through the two most prominent helical grooves; they form parallelograms which mark out the unit cells. There are six unit cells spanning the equator of the particle, corresponding to the number of subunits in the annulus[10,11].

We find a hole of about 30 Å diameter along the axis of the particle as we move outwards from the centre. This is formed probably by the packing of protein subunits in the tail core about a rotational symmetry axis. The resolution, however, is not sufficient to show up any fine periodic variations in the surface bounding this hole*. The model does show strong azimuthal fluctuations in density at two radii. Six helical tunnels of about 30 Å diameter lie at a radius of 65 Å, corresponding to the boundary between the sheath and the tail core (Fig. 5*c*). The matter which alternates with the tunnels at this radius presumably represents the connexions between tail and core. (These are to be expected, since the sheath is found in the extended state only when surrounding a core. Free sheaths are always contracted[12].)

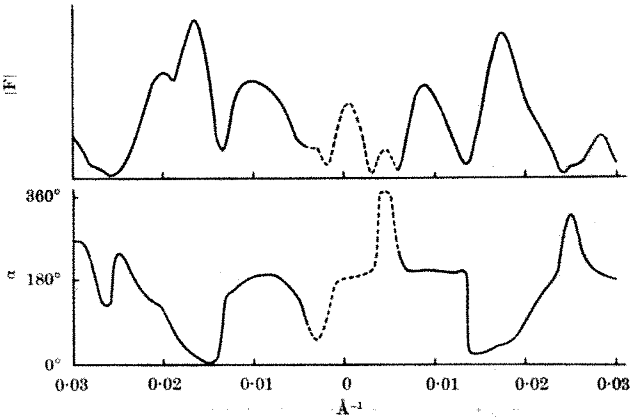

Fig. 4. Part of the computer-generated Fourier transform of the image of the tail in Fig. 1. The Fourier amplitude |F| along the second layer line is shown (compare Fig. 2), together with the accompanying phase α. The dotted parts of the curves near the middle of the diagram depend upon the exact region used to produce the Fourier transform; the regions used to produce this figure and Fig. 2 were not exactly the same.

A complex set of protuberances extends from a radius of about 90 Å to one of 120 Å at the outermost edge of the particle. They begin in the region of the model marked *L* (Fig. 5*a* and *b*) between the annuli, then sweep up to the right, as they pass through the region of an annulus, and finally join up by diagonal bridges (*S*) with the units on the upper left and lower right. The finer of the two sets of black wires near the surface passes under the bridges. The lower left-hand part of the protruding unit is almost in contact with the unit below and to the left. We cannot be sure, however, whether these units are really not in contact or whether we merely chose the contours marking the boundary between protein and stain at slightly too high a density.

Surprisingly, the cross-striations which give the appearance of annuli in the electron microscope are absent in the model. The cross-striations in the image are produced by the superposition of outer gaps and inner holes and do not correspond to deep serrations in the particle.

General Principles of Three Dimensional Reconstruction

Because of its high rotational symmetry, only a single two dimensional electron micrograph was needed to determine the three dimensional structure of the phage

---

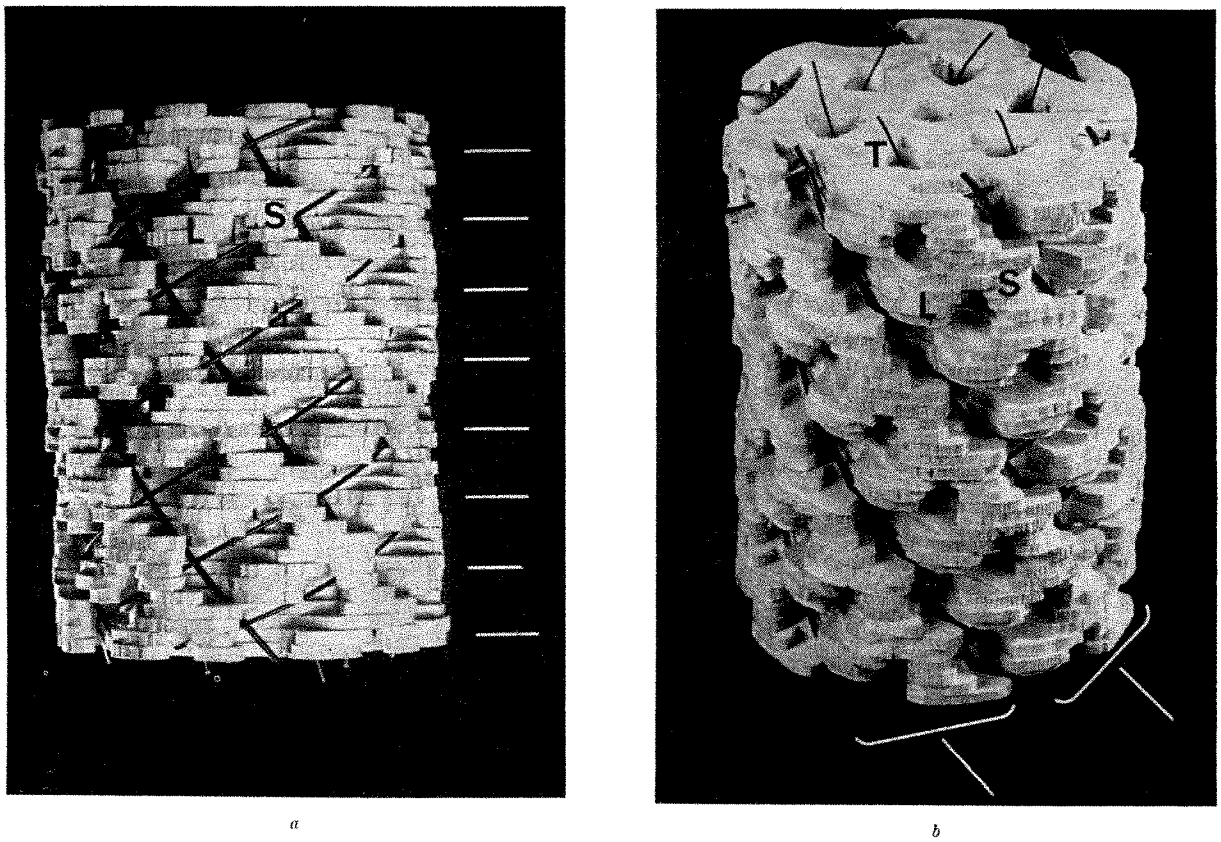
* Our method can be reformulated so as to carry out the reconstruction process without going through the intermediate stage of calculating Fourier coefficients, but this stage provides a useful point at which to check and if necessary correct the data. For example, in the case of a particle with helical symmetry like the phage tail, the relationship of the phases on the two sides of the meridian of a computer-generated Fourier transform provides a check that the axis of the particle has been correctly chosen (compare Fig. 4). If the axis were not quite correctly chosen, its position can be refined in Fourier space.

† For example, for a helical particle the three dimensional Fourier programme takes the form of a Fourier–Bessel synthesis into which the appropriate helical parameters can be inserted[3].

‡ The parallel with X-ray diffraction can be carried further, for it is possible to determine the Fourier amplitudes by optical diffraction from the electron microscope images. The determination of phases optically is more difficult, but we have tried out two optical techniques for phase determination. (1) The straightforward, but tedious, method in which diffracted rays are allowed to interfere pairwise to produce fringes, the positions of the fringe minima with respect to some reference point giving the phase. The procedure was carried out on our optical filtering system (compare ref. 2), but is very laborious and was less accurate than the densitometry method. (2) A holographic method in which the diffracted rays from the subject are allowed to interfere with a strong reference beam coming from a point in the same plane as the subject. The holographic technique using this particular geometry has been variously termed "Fraunhofer diffraction holography"[4] and "Fourier transform holography"[5]. This method has the same basis as the heavy-atom method in X-ray crystallography[6]. The method was not pursued intensively, because our first trials showed that, with subjects such as ours containing very fine detail, a proper interferometric system would have to be constructed[7].

§ Optical filtering is basically a two dimensional operation and gives direct results when applied to structures which are essentially two dimensional, such as overlapping sheets[9], thin-walled tubes (our work in preparation on the structure of the polyheads of bacteriophage *T4*; Kiselev, N. A., De Rosier, D. J., and Klug, A., work in preparation on the structure of tubes of catalase) or shallowly grooved solid objects (compare ref. 2).

* It should be stated that, in computing the map of the structure, it has been assumed that all the matter in the tail has the same symmetry. If the core had a different symmetry from the sheath, small modifications would be introduced into the model, but the main features described in this paper would be unchanged.



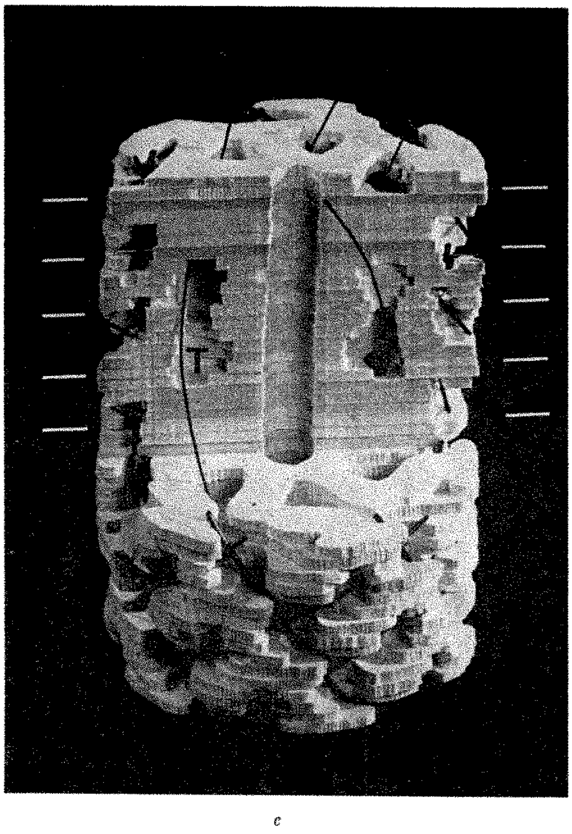


Fig. 5. Model of the phage tail in the extended state. The portion shown is about one-third of the actual length. The model was built from a series of sections in a three dimensional Fourier density map which includes data to spacings of 35 Å. *a*, Side view. The black wires lying in the prominent helical grooves on the surface serve to mark out the unit cells of the repeating structure. The horizontal lines at the side of the photograph mark the position of the annuli of subunits which can be seen in the electron micrograph in Fig. 1. *b*, Model tilted forward. The fine black wires *T* follow the path of the helical tunnels at an inner radius of about 60 Å. *c*, Same as *b*, but with part of the front half removed. The helical tunnels *T* lie between the tail core and the sheath.

The six pronounced helical ridges on the surface which run at an angle of about 30° to the particle axis (marked by brackets in *b*) can be identified with the helical "windings" which have been revealed at the surface by shadowing with metal[18]. This identification fixes the absolute hand of this family of helices. The same family of helices can be seen as the stronger of the two sets of oblique lines in the filtered image in Fig. 3, but their apparent hand is reversed there because it is the filtered image corresponding to the far side which is shown.

tail We now outline the conditions for the recovery of any type of three dimensional structure from transmission photographs and we formulate the part played by symmetry more precisely Large objects are examined usually by taking electron micrographs of thin sections, but this is not possible for small particles Instead of working with the particle directly, however, equivalent structural information in the form of its Fourier amplitudes and phases can be used If these could be measured in three dimensions, they could be used in a Fourier synthesis to compute the structure itself

The electron microscope image represents a projection* of the three dimensional density distribution in the object at all levels perpendicular to the direction of view According to a theorem familiar to crystallographers, the Fourier coefficients calculated from a projection of a three dimensional density distribution form a section through the three dimensional set of Fourier coefficients corresponding to that distribution By collecting many different projections of a structure in the form of electron microscope images, it should therefore be possible to collect, section by section, the full set of Fourier coefficients required to describe that structure (Fig 6) The number of projections needed to fill Fourier space roughly uniformly depends on the size of the particle and on the resolution, in much the same way as the number of zero-layer precession photographs in a three dimensional X-ray analysis depends on the unit cell size and the desired resolution Similarly, rotation or screw symmetry reduces the number of sections required, because different orientations of the particle present identical projections† The advantage of symmetry is illustrated in Table 1 which gives the number of independent views required to solve, to a resolution of about 30 Å, comparable structures of linear dimensions of about 250 Å

Table 1

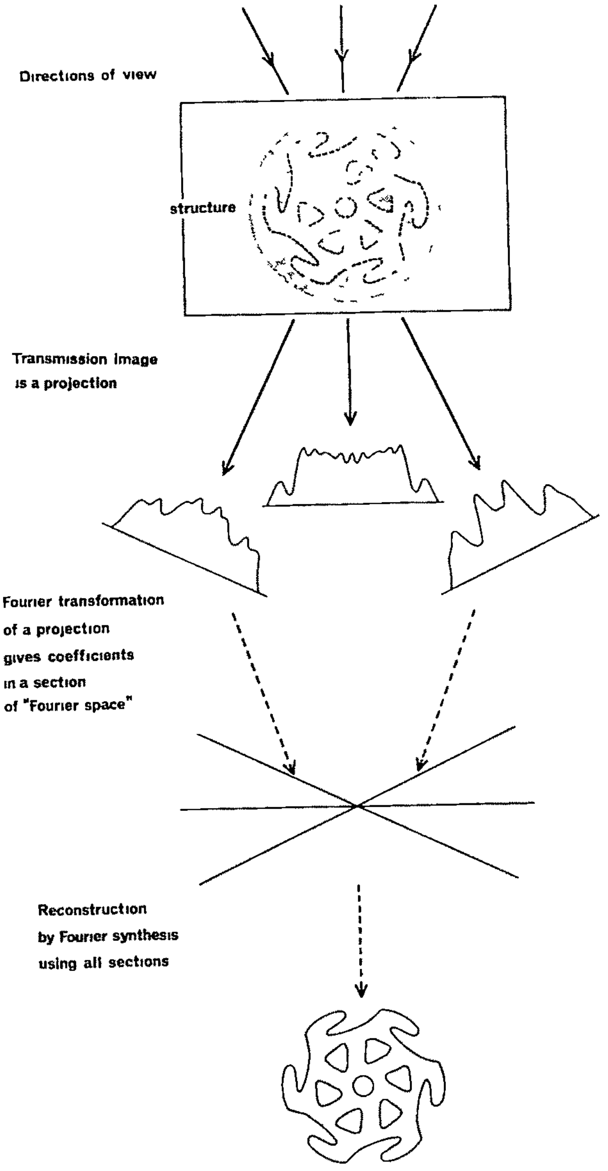
Symmetry class	Example	No of views
Helical	*T*4 phage tail	1
Icosahedral	Tomato bushy stunt virus	~2
No symmetry	Ribosome	~30

It may be helpful to restate the role of symmetry differently The projection of an object with rotational symmetry is the sum of projections of its asymmetric unit in the various symmetry-related orientations (and positions) In the reconstruction process the three dimensional structure of the asymmetric unit is recovered from the various projections of it which are contained in a single image of the whole object Looked at in this way, an electron microscope image of the phage tail, which has forty-two subunits in its axial repeat, effectively presents projections of the subunit in twenty-one different orientations, more than enough to reconstruct the structure‡ The simplicity introduced by the symmetry of the phage tail made us choose it for our first attempt at three dimensional electron microscopy

At this point, it is worth discussing the reason why high-resolution stereo-electron microscopy is not, in general, an adequate technique for solving a structure Stereo-microscopy does not reproduce structures in a quantitative and tangible form, and has other drawbacks Information from pairs of corresponding points in a stereo-pair is combined visually Even if one had ideal pictures in which point-like features were clearly resolved, some points in a complex, deep structure would probably be obscured by others in front of them. To overcome this difficulty, many pairs of stereo-pictures would have to be taken This brings one back to the requirements discussed above, but the procedure does not tell one how these views might be combined, even subjectively. For these reasons, stereoscopy is only suitable for seeing details confined to the neighbourhood of a single surface or for particularly simple three dimensional objects

General Requirements for Implementation

If more than one projection of an object is needed to resolve its structure, such projections can be obtained in two ways The most obvious one is to systematically tilt



Directions of view
structure
Transmission image is a projection
Fourier transformation of a projection gives coefficients in a section of "Fourier space"
Reconstruction by Fourier synthesis using all sections

Fig 6. Scheme for the general process of reconstruction of a structure from its transmission images

and photograph a single particle in the electron microscope If all the necessary projections are collected regardless of particle symmetry, no assumptions are needed to calculate the three dimensional structure The synthesis will reproduce any symmetry that the particle possesses, but also any distortion it has suffered, or any irregularity in the stain distribution These defects, however, can be detected by comparing Fourier syntheses of different particles For a complete set of projections, the particles must be tilted accurately by small increments to a total tilt angle of 180° This, however, presents the technical problems both of covering the complete range of angles and of preserving the structure during successive exposures to the electron beam Symmetry lessens the difficulties by reducing both the number of different projections and the maximum tilt angle required So that symmetry can be used, the orientations of the symmetry axes with respect to the tilt axes must be found

---

* In precise terms, it is the logarithm of the intensity of the transmitted electron beam in the image which represents the projection of the three dimensional distribution of absorbing (strictly scattering) material along the path of the beam For a distribution $\varrho(x, y, z)$, the transmitted intensity I is, in conditions of single scattering of electrons, related to the incident intensity I_0 by the expression $I(x, y) = I_0 \exp[-\mu \int \varrho(x, y, z)\, dz]$, where μ is the mass absorption coefficient and z is measured along the direction of the beam This interpretation on a mass-thickness basis is, of course only valid if the stain is amorphous[14], and if the spatial order in the liquid-like arrangement of scattering atoms is not shown up at the resolution with which one is concerned in the image[15] This condition is obeyed for the scale of structure normally investigated in biological applications of electron microscopy Likewise the condition of single scattering is obeyed for the thicknesses of stain involved

For our quantitative work a measure of the transmitted electron beam is given by the optical density on the electron microscope plate which is proportional to it[16] Thus in effecting the Fourier transformation of the electron microscope images, logarithms of the optical densities should be used to obtain the Fourier coefficients of the structure $\varrho(x, y, z)$ Taking the logarithm is easy in numerical processing, but presents a problem when optical methods are used to measure Fourier amplitudes and phases, for the logarithm of transmitted intensity in an optical system is directly proportional to the optical density and not to the logarithm of the optical density

† This statement assumes that the distribution of stain possesses the particle symmetry (for example, it could have the form of a cylinder for a helical particle) Departures from this must be taken into account, and the technical problem will be discussed elsewhere

‡ In terms of helical diffraction theory the amplitude of the Fourier transform of the phage tail has cylindrical symmetry to the working resolution because there is no overlap of Bessel functions of different order on the layer planes[17]

Alternatively, different images from a field of particles are, in principle, projections of the same structure (although in practice allowance must be made for variations in staining or perturbations in the different particles) The exact orientation of each particle in relation to the direction of view must be determined in order to relate correctly the Fourier space section obtained from it to those obtained from other particles This would mean determining the orientation of the particle for each image before its exact structure is known In practice, ancillary tilting experiments would help in the recognition of the views[18,19] Recognition and determination of the angle of view might be done more precisely by some form of refinement process, such as the simulation of particle images using a provisional model of the structure[18,19]. This would also help in assessing the preservation of detail in the different images It is important to integrate the information contained in the images of different particles so that the effects of noise coming from the sources mentioned above can be averaged out

Concluding Remarks

Our method of three dimensional reconstruction relates the analysis of electron microscope images to the theory that has been developed for X-ray diffraction analysis The difference is that the "phase", which together with the amplitudes of the Fourier components allows the reconstruction of a three dimensional map, is lost in recording the X-ray diffraction data It is preserved, however, by the focusing of the diffracted electron beam into an image At the same time, one can work with a single or a few particles and one is not confined to working with highly ordered crystals or fibres as in protein crystallography. While small numbers of particles can be used, more variability must be expected than is encountered in the average structure from, for example, a protein crystal containing 10^{15}–10^{17} particles*

Because the theory underlying this method is a very general one, the method can be used for all kinds of objects It may be necessary, however, to modify the various procedures used according to the particular problem. In the example given here we have used single particles, but the method could work equally well with ordered aggregates or arrays such as sections of muscle or small crystals

We thank Dr J. T Finch for the electron micrographs, R A Crowther for programming the densitometer and for help with the computer processing, Dr K C Holmes for making his Fourier–Bessel programme available and Miss Marion Holder for technical assistance We also thank Professor Gill and the manager of the Computer Centre, Imperial College of Science and Technology, for making facilities available We thank Drs H E Huxley and M F Perutz for helpful criticism of earlier versions of this article. One of us (D J De R) was aided by a grant from the American Cancer Society

Received January 3, 1968

* Because the preservation of detail in electron micrographs is not usually perfect, many examples must be examined and assessed The method of optical diffraction[1] provides an objective assessment of the information contained in an image of a periodically repeating structure, for it displays an average of the genuine, repeating features We have found by this technique that the resolution in electron micrographs of negatively stained biological specimens can be as high as 15–20 Å (refs 1 and 2)

Response of Pine Seedlings to Mechanical Stimulation

by
W. C. ASHER
Southeastern Forest Experiment Station,
US Forest Service Research,
Triangle Park, North Carolina

When needles of pine seedlings are deflected downwards there is an electrical response which can be measured.

WHEN developing electrophysiological techniques for forest tree physiology research, I observed a hitherto unreported electrical "response" to leaf fascicle movement in young slash (*Pinus elliottii* variety *elliottii* Engelm) and loblolly (*P taeda* L) pine trees The effect can be elicited consistently by sharply deflecting a fascicle downward while recording the electrical potential between two or more points on the stem of the tree with non-polarizing electrodes The response is rapid and sharply defined and seems to be typical of tissue depolarization

A tracing of a single recorded response, obtained from a 2 yr old potted loblolly pine seedling is shown in Fig 1 Electrical potentials were led off through cotton-wick tapwater bridges to Ag–AgCl electrodes, amplified by a Keithley 603 d c. electrometer-amplifier (input resistance 10^{12} ohms), and displayed on a potentiometric recorder Conventional high impedance d c amplification and oscilloscope recordings were also made frequently In the case of Fig 1, the stimulated fascicle was located about midway between the apical and basal electrode contact points The input system was floating, with a resistance to earth of about 10^{10} ohms Single-ended inputs, and earthed seedlings with differential inputs, gave the same results

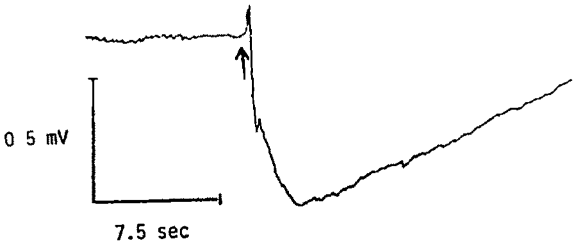

Fig 1 Response of *Pinus taeda* seedlings to needle fascicle deflexion Arrow indicates approximate time of stimulation Peak at right of arrow illustrates the initial fast component of the response A downward response indicates electrical negativity of the apex of the seedling with respect to the base

The magnitude of the response to maximal stimulation varied considerably with the condition of the tree and among trees, but an average of 406 measurements taken on eight seedlings was 0 72 ± 0 58 (standard deviation) mV, a typical response In a series of forty-five measurements on two trees, with a Keithley 603 d c electrometer-amplifier and a direct-coupled Tektronix *RM* 565 dual-beam oscilloscope the response lasted on average 22 0 ± 5 9 sec Most of the fascicle deflexions in this series were produced by means of a shielded pulse-driven d c solenoid with its armature attached to the needles by means of a string or light plastic rod No differences in the amplitude or duration of the response were attributable to tree species.

Effects of Deflexion

A brief description of a recent set of experiments employing two amplifying and recording channels (*A* and *B*) illustrates typical features of what has been observed so far Ag–AgCl electrodes were attached by cotton threads soaked in 0 001 molar KCl to three points on a 2 yr old potted loblolly pine seedling in the laboratory One electrode (apical) was placed on the terminal bud of the seedling and led to the "positive" input terminal of amplifier *A* A second electrode (middle), contacting the stem about midway, was connected in common with the "negative" input terminal of amplifier *A* and the "positive" side of amplifier *B*. The third (basal) electrode led from a point near the base of the seedling to the "negative" input terminal of amplifier *B* Outputs from the two amplifiers were connected separately to two adjacent channels of a four-channel Texas Instruments Servo-Riter recorder

Deflexion of a fascicle near the middle (common) electrode drove this point negatively (depolarization) Stimulation between this point and the apical contact resulted in depolarization of the tissue at the apical electrode, whereas stimulation between the middle and basal contacts gave the same result as stimulation at or near the middle electrode Stimulation in the immediate vicinity of an electrode contact usually produced a negative-going response at that point Stimulation between two electrodes produced a negative-going potential change at the upper or apical contact point Stimulation of fascicles on branches produced no detectable response at electrodes on the main stem or on other branches, but the usual responses were obtained from electrodes on the affected branches Responses appeared on lateral branches above the point of stimulation on the main stem, but not on those below this point

"Dead" seedlings did not ordinarily show a response. The difficulty of killing a seedling without affecting the elasticity of the tissue. and of determining precisely when a seedling is actually dead, renders a definite statement on this point impossible at present.

Girdling the stem with a hot wire above or below the point of stimulation resulted in altered response curves, ranging from disappearance of the initial fast component (Fig 1) to reversal of polarity. The most consistent effect noted was reversal (from negative-going to positive) on destruction of stem tissue between the point of stimulation and the basal electrode contact. Transverse knife cuts into the xylem immediately above and below the stimulated fascicle resulted in the disappearance of the initial rapid component of the response, but the slow or prolonged component persisted unaltered.

Application of electrolyte solutions (for example, 1–3 molar KCl) to the point of fascicle attachment to the stem usually led to a greatly reduced electrical response (Occasional absence of this effect in a few early records was apparently caused by failure of the solution to penetrate into the living tissue) Solutions of non-electrolytes, distilled water and mineral oil have not shown any effect on response amplitude Application of 0 1–1 normal KCN resulted in a marked reduction in amplitude, but this may have been principally a result of electrical shorting by the electrolyte rather than any metabolic effect In all cases, response amplitudes returned to pretreatment levels after drying or flushing of the point of application with distilled water

Characteristics of the Responses

General characteristics of the observed responses can be summarized as follows (*a*) Stimulation at intervals of about 20 sec produced maximal reproducible responses Increasing the stimulus rate produced responses arising from the point of recovery to the previous response, but with reduced amplitude Stimulus intervals of 5 sec or less led to a sustained depolarization with small transient "responses" that were probably stimulus artefacts

(*b*) No precise measurements of mechanical stimulus intensity or rate of stimulus onset were attempted, but actuation of the solenoid armature by square current pulses of varying amplitudes and by a voltage ramp of variable slope applied to the coil indicated an "all-or-none" type of response rather than a graded one Current pulses of about 4 m amp or less gave angular fascicle deflexions of less than 30 degrees and resulted in small transient and atypical voltage fluctuations, whereas pulses of 5 m amp or more moved the fascicles at least 45 degrees and led to the typical maximal response Similarly, response to a slow rate of stimulus onset (voltage ramp applied to the coil), if there was any, was maximal and showed the rapid initial potential change associated with sudden fascicle deflexions (*c*) Efforts to establish the magnitude of the delay between stimulus and response have so far been unsuccessful There was a slight delay, but it was difficult to measure because of the nature of the method of mechanical stimulation With very rapid deflexions, measurements from photographs of oscilloscope traces gave values of about 2 m/sec, which is far more rapid than any previously reported conduction times for plant action potentials Attempts to utilize electrical stimulation were made, but without success

(*d*) The magnitude of the recorded response did not seem to decrease appreciably with distance from the point of stimulation, although the response from a fascicle very near a recording point (within 1 cm or less) was usually greater than at more distant points. Spatial decrement could thus very well be exponential near the fascicle.

(*e*) The effect of temperature on the responses was not studied systematically, but casual observation indicated that the relationship, if any, was slight.

I have not succeeded in finding a fully plausible explanation for these observations. The possibility of shifting electrode contacts has been thoroughly tested and ruled out. Regardless of type of contact used (for example, cotton wick, chlorided silver or platinum wires inserted into the stem or clamped in place), the response persists unaltered. Furthermore, the consistent return of the potential to pre-stimulus levels within a few seconds argues against electrode contact shift as a significant contributing factor.

Similarly, electrostatic artefacts were eliminated by earthing the seedling, and puffs of air directed against the fascicles with sufficient force to deflect them produced the same response as mechanical contact. Electrical noise ("cable noise") resulting from mechanical tissue deformation does not seem to explain the phenomenon either, because of the relatively long recovery period.

Possible Explanations

There are at least three other possibilities, two of them essentially biological rather than physical. First, the response could be caused by depolarization of stem tissue in the immediate vicinity of the fascicle base. If the overall longitudinal seedling biopotential is the algebraic sum of polarized cells in a series-parallel equivalent circuit[1], the drop in potential difference resulting from slight injury in the area including the base of the deflected fascicle would account for the observed response. This would be true especially in those cases where the overall potential difference is in the direction of apical positivity with respect to the base of the seedling, and the response is negative, that is a reduction in potential difference. In those cases where the seedling apex is electronegative with respect to the base, however, the response should be recorded as "positive" (toward zero). Such a clearcut relationship has not been established, although positive responses are usually, but not always, associated with apical negativity.

Second, the response could be a rapidly propagated electrical impulse. All attempts to establish a reasonable transmission time have, however, proved fruitless. If a delay exists it is so slight as to cast serious doubt on its biological significance.

Finally, the mechanical deformation produced by flexure of the point of fascicle attachment could produce sudden changes in hydrostatic pressure within the tree, possibly altering cell membrane permeability at distant electrode contact points and thus producing the observed electrical changes. If this is indeed the case, the action must be strongly directed acropetally, posing intriguing anatomical and morphological problems.

Jacobson[2] has recently reported what he refers to as a "negative receptor potential" in response to mechanosensory hair stimulation in *Dionaea muscipula* Ellis (Venus fly-trap). Although his method of recording differed slightly from mine in that he recorded directly from the sensory hair, his negative receptor potential bears a marked resemblance to the potentials reported here both in waveform and duration (the *Dionaea* potentials were of greater magnitude, perhaps because of the recording method used).

A similar potential change after a series of stroking stimuli had been applied to the outer leaf blade of *Dionaea muscipula* is apparent in the recording contained in a report by DiPalma *et al*.[3] The authors suggest that small protruding structures (stellate trichomes) on the leaf surface serve as touch receptors to sensitize the trigger hairs to mechanical stimuli.

It is possible then that an electrical potential change is generally associated with mechanical displacement of such plant structures as hairs, needle fascicles, stellate trichomes and other similar organs.

I thank Dr Bruce I. H. Scott for his encouragement and advice.

Urinary Metabolites in Parkinson's Disease

by

FREDERICK A. KUEHL, jun.
W. J. A. VANDENHEUVEL
ROBERT E. ORMOND

Merck Institute for Therapeutic Research,
Rahway, New Jersey

Although DMPEA does not seem to be a component of the pink spot in Parkinsonism, high urinary concentrations of tryptamine may be associated with some cases of the disease. This suggests that in such cases tryptamine hydroxylation is defective.

FRIEDHOFF AND VANWINKLE reported in 1962 that a compound characterized as 3,4-dimethoxyphenethylamine (DMPEA) by its paper chromatographic behaviour and a colour reaction (pink spot when treated with a sequence of reagents believed to be specific for phenethylamines), was unique to the urine of schizophrenic individuals[1]. Both the identification of the urinary component and its relationship to schizophrenia, however, have become controversial issues. Sen and McGeer found the amine in the urines of eleven out of twenty-two schizophrenics[2], and Bourdillon *et al* observed a substance like DMPEA in several urines from schizophrenics[3]. Others, however, have been unable to correlate DMPEA or the pink spot or both with this disease (for leading references see ref. 4).

We, too, could not obtain unequivocal evidence for or against the presence of 3,4-dimethoxyphenethylamine in the urine of schizophrenics using the Friedhoff technique because of the presence of other components in the same region of the paper chromatogram[5] An improved system of isolation[5] based on thin-layer chromatography has made it possible for us to effect a more selective separation of the urinary amines, indeed, the pink spot area of a paper chromatogram prepared by the Friedhoff technique invariably revealed the presence of several components when rerun in our thin-layer system[5] With this method, our studies of the urines of schizophrenics obtained from Dr Friedhoff tended to confirm his findings that DMPEA is unique to the urines of some schizophrenic patients More extensive investigations of a larger number of urines from other sources failed, however, to confirm these findings and we concluded that the positives in the first group were attributable to unique nutritional or environmental factors not related to schizophrenia[6].

To pursue these studies further, urines of normal and schizophrenic individuals were examined for 3,4-dimethoxyphenylacetic acid, the principal metabolic end product[7–9] of 3,4-dimethoxyphenethylamine The results of these studies showed low concentrations of the acid in urines of both normal and schizophrenic individuals, and no significant difference between the two groups On the basis of this evidence it was concluded that the excretion of DMPEA is not characteristic of schizophrenia[6] Friedhoff and Furiya recently reported finding the acid in the urine of both types of individuals, although the concentrations they found were considerably greater than we observed[10] Despite the final statement in their paper that they continue to find DMPEA only in urines of schizophrenics, our conclusion seems to be supported by a number of recent publications[11–15], and the suggestion that the pink spot is a "red herring" when applied to the schizophrenic state seems to represent an accurate appraisal of this situation[16] Most recently Perry *et al* have suggested that the pink spot may be monoacetyl or monopropionylcadaverine[17]

Although a relationship between DMPEA and schizophrenia now seems doubtful, recent evidence has suggested that this amine has some significance in Parkinson's disease Barbeau and his associates, using the Friedhoff technique, found that urines of 80 per cent of patients afflicted with this disease contained the pink spot component—tentatively identified as DMPEA[18] They were also able to show that administered DMPEA causes akinesia-like symptoms in animals[19] A programme to examine the pink spot components in urines of patients with Parkinson's disease with the technique employed in our earlier studies was thus undertaken with the co-operation of Dr Barbeau After this research was initiated, other workers confirmed Barbeau's findings concerning the incidence of a pink spot in urines of Parkinsonians, but could find no evidence supporting its identification as DMPEA[20].

The Parkinson urines, obtained from two sources and from patients who had been off drug treatment for 48 h before collection, gave the results shown in Table 1 Seven out of seventeen gave significant pink spots when examined by the Friedhoff technique An additional seven were positive in this respect, but here the colour was not judged to a greater intensity than observed for some normal urines None of these urines showed detectable amounts of DMPEA when examined by thin-layer chromatography Confirmation of the absence of this amine was obtained by gas chromatography of specimens selected on the basis of a high intensity pink spot The acid fractions of these urines were examined for 3,4-dimethoxyphenylacetic acid by the method described before[6], no differences between the normal and diseased groups were observed, which agrees with the absence of significant amounts of the precursor amine

Boulton *et al* have suggested that the pink spot in urines of schizophrenics and Parkinsonians may be *p*-tyramine, for they observed this compound to exhibit chromatographic and chromogenic properties in the Friedhoff system similar to those of DMPEA, and it was found in a single pooled specimen from four Parkinsonian patients in approximately twice the concentration found in that of a schizophrenic[21] Unfortunately, the current studies with Parkinson urines were not run in such a manner that *p*-tyramine could be detected On the other hand, our investigations revealed that tryptamine is both isographic with DMPEA in the Friedhoff system and characterized by a similar although not identical colour sequence when treated with the ninhydrin-modified Ehrlich reagents It would thus contribute to the overall colour of the spot, which on paper is diffuse and masked by neighbouring contaminants Accordingly, extracts of urines from a number of Parkinson patients were subjected to paper chromatography and the pink spot zone was eluted from paper with methanol and analysed by thin-layer chromatography Certain of the urinary extracts were also analysed directly by this method The results shown in Table 1 demonstrate that there is a reasonable correlation between the colour intensity of the pink spot on the paper chromatogram and the tryptamine content as measured by thin-layer chromatography (confirmation of the presence of this amine was obtained by gas chromatography), certainly enough to suggest that tryptamine is one of the principal components of the pink spot

Table 1

Urine	Pink spot by paper strip	Tryptamine estimate by TLC
11–W	5	3
9–W	4	3
10–W	3	1

3–N	0	0

The suffix W denotes a sample from Dr Waltz, B from Dr Barbeau and N a normal urine specimen An arbitrary value of 0 to 5 was used to estimate the intensity of the pink spot on paper and the tryptamine spot on the thin-layer chromatography (TLC)

In conclusion, our studies with urines of Parkinson patients have revealed that DMPEA is not a component of the pink spot, nor is there any consistent qualitative difference between the urines of normal and diseased individuals examined with respect to the composition of the pink spot On the other hand, the urines of patients which showed the more intensely coloured spots were also found to have correspondingly high concentrations of tryptamine Thus it seems possible that high urinary concentrations of tryptamine are associated with some but not all cases of Parkinson's disease, and that this amine is a principal component of the pink spot observed in these cases Furthermore, the finding by Barbeau *et al* that the urinary excretion of 5-hydroxyindoleacetic acid is diminished in patients with Parkinson's disease[22] is compatible with the concept of an increased excretion of tryptamine, and it is therefore reasonable to suggest that tryptophan hydroxylation may be defective in this diseased state Indeed, the administration of 5-hydroxytryptophan is reported to improve some symptoms of Parkinson's disease (personal communication from A Barbeau). Of further interest are the observations that brain concentrations[23] and the urinary excretion[24] of dopamine are decreased in Parkinson patients The fact that administered DOPA improves some symptoms led Cotzias *et al.* to suggest that tyrosine hydroxylation, the rate limiting step in dopamine formation, may be defective in this disease[25] Such a fault would be expected to result in an increased excretion of *p*-tyramine and, as noted here, Boulton *et al* have found that this amine is a component of the pink spot from Parkinson patients[21]. If both tyrosine and tryptophan hydroxylation prove to be deficient in Parkinson's disease, such a defect could be attributable to many factors including low concentrations of the individual hydroxylases Because, however, a reduced pteridine[26,27] is an obligatory requirement for both tyrosine and tryptophan hydroxylase it is possible that a deficiency of this cofactor may also be rate limiting and thus of significance in the aetiology of this disease

We thank Professor André Barbeau and Dr Joseph M Waltz for the urines of Parkinson patients

Late DNA Synthesis in Heterochromatin

by

A. LIMA-DE-FARIA*

HALINA JAWORSKA*

Molecular Cytogenetics Laboratory,
Institute of Genetics,
University of Lund,
Sweden

It seems to be a rule of chromosome replication that heterochromatin synthesizes its DNA at a later stage than the rest of the chromosome.

UNTIL 1959 heterochromatin was considered to be an elusive chromosome material difficult to approach experimentally at the cytological level[1]. Work with phosphorus-32 and tritium had not then produced any relevant information about this chromosomal material.

The first experimental demonstration that heterochromatin synthesizes its DNA later than the euchromatic regions of the chromosome complement was obtained in the grasshopper *Melanoplus differentialis*[2,3] In the male of this species there is a large heterochromatic *X* chromosome at prophase The autosomes are chiefly euchromatic The injection of tritiated thymidine into the body cavity revealed that in the spermatocytes, at zygotene and pachytene, the heterochromatic *X* and the autosomes were labelled at different times In the testicular tubules the spermatocytes are grouped in cysts which are synchronized at a given meiotic stage. The cysts move along the tubule as meiosis progresses, so that, from their relative position, it is possible to tell which have developed the farthest. In sections of this material, the spermatocytes of the cysts which were at a late stage in development were labelled only in the heterochromatic *X* chromosome, whereas cysts at an earlier stage of development were only labelled in the autosomes This result established that heterochromatin in this species, and in this tissue, replicated later than euchromatin

To find out whether this phenomenon occurred in other organisms, leaves from seedlings of rye (*Secale cereale*) were exposed to tritiated thymidine In this organism[4,5] all chromosomes are heterochromatic on both sides of the kinetochore and possess heterochromatic "knobs" at most ends The autoradiographic picture of interphase nuclei showed that in this species heterochromatin also replicated at a different time from euchromatin[16] Since then many people have studied the same phenomenon in plant, animal and human material by tritium autoradiography

Cytology of Heterochromatin

Heterochromatin as originally described by Heitz[7] represents a differential behaviour of the chromosome phenotype Heterochromatic regions are characterized, in interphase and early prophase nuclei, as "chromosome regions that form massive blocks of Feulgen positive material"[12].

---

* Present address Institute of Animal Genetics, Edinburgh

Heterochromatin is a state of the chromosome rather than a substance, as is sometimes assumed, because it does not occur at all stages of development In *Drosophila*, heterochromatin is absent in the early embryonic stages, but it is found at later stages in the three largest chromosomes[13] In the male of the grasshopper *Melanoplus* the X chromosome is not heterochromatic in the spermatogonia, but becomes so later in the spermatocytes

As Schultz[12] pointed out, "nucleic acid starvation"[14] or "negative heteropycnosis"[15] should not be included in heterochromatin If we do so, every differential state of the chromosome during the cycle of division could qualify as heterochromatin The original definition would break down, everything in the chromosome becoming heterochromatin depending on the appearance of the region used as a standard Recent results confirm the idea that negative heteropycnosis is a phenomenon distinct from heterochromatin

Spectrophotometric measurements have shown that the amount of DNA per unit area is two to three times greater in the heterochromatin than in the euchromatin of the same nucleus[16] This is not the case in negatively heteropycnotic regions in which there is no indication of increase or decrease in DNA content[17]. Thus this result contradicts the assumption that negative heteropycnosis is the reverse state of positive heteropycnosis, a term also used for heterochromatin. Furthermore, autoradiographic studies in *Trillium* disclose that cold-induced negative heteropycnotic regions can occur in chromosomes which had completed their DNA synthesis before the cold treatment began[18] This result, as well as the spectrophotometric measurements, shows that the designation sometimes given to such chromosomal segments of "nucleic acid starved regions" does not describe appropriately the actual macromolecular organization of these regions.

Negative heteropycnosis is thus not necessarily the opposite of heterochromatin, although it is a particular state of the chromosome, and probably an equally significant one Furthermore, it is not in agreement with the available evidence to call heterochromatin "positive heteropycnosis" as it has sometimes been described We should keep the original description of this well defined state of the chromosome which is characterized by the appearance of a massive block of Feulgen positive material at a given stage of development Other states of the chromosome should be considered as separate phenomena until we have a better knowledge of the macromolecular organization of the chromosome during these states

Autoradiography and Heterochromatin

Information about DNA synthesis obtained by different laboratories using tritium autoradiography has varied in the degree of accuracy with which the relation between the autoradiographic picture and the occurrence of heterochromatin has been established in a given tissue Accordingly, these results may be divided into three main groups (*a*) Autoradiographic studies were carried out in the same tissue and at the same stage at which heterochromatin has been well established (*b*) Tritiated thymidine was administered to tissues where heterochromatin was not recognizable but the chromosomes studied were heterochromatic in another tissue (*c*) Tritiated thymidine was added to a given tissue, but no exact information was available about the occurrence of heterochromatin in the tissue studied or in other tissues This group contains some of the results for sex chromosomes or presumed sex chromosomes

The experiments of groups (*b*) and (*c*), although relevant to this problem, cannot be considered to give reliable information about the relation between the occurrence of heterochromatin and the sequence of DNA synthesis To establish this relation with accuracy it is necessary (i) that there is clear-cut evidence that a given chromosome or chromosome segment is actually heterochromatic, and (ii) that the autoradiographic pictures are studied in the tissue where heterochromatin is displayed

A well known phenomenon, since Heitz's discovery of heterochromatin, is that a given chromosome is not necessarily heterochromatic in all the tissues of an organism, and that not all sex chromosomes are heterochromatic

Relation between Heterochromatin and Late Replication

In this article, we will deal chiefly with the evidence from the first group of results, where the two conditions just postulated are fulfilled. There are now many results in this category available from different laboratories These allow us to assess the general validity of the findings originally made in *Melanoplus* and *Secale*

Four species of plants (Table 1) have been found to exhibit this phenomenon *Secale cereale*[19,20], *Fritillaria lanceolata*[21], *Vicia faba*[22] and *Hordeum vulgare*[23] In these species heterochromatin is displayed, in root and leaf nuclei and other tissues It shows up at interphase in the form of chromocenters and at prophase as large chromomeres or deeply stained segments Tritiated thymidine was administered to these tissues and the autoradiographic picture was studied at interphase, prophase and metaphase In the four species, the chromocenters at interphase, the large chromomeres at prophase and the corresponding regions at metaphase were found to replicate later than the euchromatic regions (Table 1).

Four species of insects (Table 2) exhibit the same phenomenon *Melanoplus differentialis*, *Bombyx mori*, *Pseudococcus obscurus* and *Drosophila melanogaster* Three of them, *Drosophila*, *Melanoplus* and *Pseudococcus*, are classical examples of organisms with heterochromatin The behaviour of the X chromosome in *Melanoplus* was mentioned earlier in this article In *Drosophila*, the heterochromatin of which was initially studied by Heitz[7–11] at

Table 1 PLANTS IN WHICH INCORPORATION OF TRITIATED THYMIDINE WAS STUDIED IN THE SAME TISSUE AND AT THE SAME STAGE AND WHEN HETEROCHROMATIN HAS BEEN WELL ESTABLISHED

Species	Autoradiography		Heterochromatin		Replication period of heterochromatin	References, autoradiography	References, heterochromatin
	Tissue	Stage	Tissue	(1) Stage (2) Chromosomes			
Secale cereale	Leaves Roots	Interphase Prophase Metaphase	Leaves Roots	(1) Interphase Prophase (2) Proximal, and median regions of all chromosomes and "knobs"	Later than euchromatin	19, 20	6, 64, 65

Vicia faba	Roots	Interphase	Roots	(1) Interphase Prophase (2) Near centromeres and other regions	Later than euchromatin	22	66
Hordeum vulgare	Roots	Metaphase	Roots	(1) Interphase Prophase (2) Proximal regions of all chromosomes	Later than euchromatin	23	65

prophase and metaphase in somatic cells, the whole *Y* chromosome, the proximal regions of the *X* and of chromosomes II and III are heterochromatic The incorporation of tritiated thymidine into this same tissue where heterochromatin is observed reveals the late replication of the heterochromatic regions relative to the euchromatic ones[24]. Particularly striking is the case of *Pseudococcus* where a whole set of chromosomes is heterochromatic[25]. This whole set undergoes DNA replication later than the euchromatic set in the same nucleus[26] In *Bombyx*[27], heterochromatin in the spinning glands is also found to be late replicating when tritiated thymidine is administered to this tissue In the four cases the autoradiographic picture was studied in the same tissue and at the same stage, when the heterochromatin was described

Mammals, including man, give most examples confirming the rule of late replication of heterochromatin We include in Table 3 only the cases where DNA replication has been studied in the chromocenters at interphase With the exception of a few cases, only such conditions allow an accurate study of the sequence of DNA replication in heterochromatin relative to euchromatin Only when the information from the chromocenters at interphase, or from heterochromatic chromosomes at prophase, can be directly related to specific chromosomes at metaphase can we state that the late DNA replication seen at metaphase is representative of the heterochromatin observed at interphase or prophase Metaphase chromosomes are seldom heterochromatic

Man is the species in which the relation between the metaphase and interphase pictures has been best established because of the occurrence of individuals with multiple *X* chromosomes The number of chromocenters (Barr bodies) seen at interphase in diploid cells is equal to the number of *X* chromosomes minus one (according to the rule of Harnden[2]) Thus in man the autoradiographic picture of the *X* chromosome at metaphase can be considered to furnish reliable information about the late DNA replication of heterochromatin[29–31] Studies of DNA replication in individuals with multiple sex chromosomes have confirmed the relation between the number of Barr bodies seen at interphase and the number of late replicating *X* chromosomes present at metaphase[32–38] Furthermore, there have been several studies of the tritium autoradiographic picture of Barr bodies at interphase which confirm the late replication of heterochromatin in man at the chromocenter stage[39–41] In addition to the sex chromatin (Barr bodies), autosomal heterochromatin has also been described at interphase in the human male and female This replicates at a different time from the euchromatin[42,43]

The Chinese hamster (*Cricetulus griseus*) has *X* and *Y* chromosomes which form distinct chromocenters at interphase (ref 43 and personal communication from W Schmid) These were found to replicate later than the euchromatic regions of the autosomes in interphase nuclei and at metaphase[44,45] A similar situation is found in the Syrian hamster (*Mesocricetus auratus*) and in the guinea-

pig (*Cavia cobaya*), in which several major and minor chromocenters, present in the interphase nucleus, have been found to replicate late relative to the euchromatin[46].

The sex chromosomes of *Microtus agrestis*[47] are among the largest known in mammals and their heterochromatin can be seen at interphase in the form of very large chromocenters and at prophase. In the male chinchilla[48], the *Y* and the *X* chromosome are heterochromatic at interphase forming two large chromocenters. In these two species the pattern of uptake of tritiated thymidine into DNA was studied at metaphase, and also at interphase where the distinct chromocenters were found to replicate later than the euchromatin.

In the dog[49], the donkey–grevy zebra hybrid[50] and in the mouse[51] there are one or several chromocenters at interphase. These represent either one *X* chromosome (dog and donkey–grevy zebra hybrid) or cannot be directly related to sex chromosomes (mouse). In every mammalian species included in Table 3 the autoradiographic picture and the heterochromatin were studied in the same tissue at interphase, disclosing the late replication of the chromocentral heterochromatin.

Rule of Chromosome Replication

These results for the seventeen species of plants, insects and mammals (Tables 1–3) allow us to formulate the following rule of chromosome replication. When tritiated thymidine is incorporated into the cells of a given tissue in which there are massive Feulgen positive chromosome regions at interphase or early prophase, the heterochromatic regions replicate their DNA later than the euchromatic segments. This takes place when the autoradiographic picture is studied in the same tissue and at the same stage in which heterochromatin is displayed. This phenomenon occurs irrespective of the evolutionary position of the organism and of the tissue in which heterochromatin is observed.

If a chromosome is heterochromatic in a given tissue and replicates its DNA later than the euchromatin, it does not necessarily follow that it replicates its DNA later in other tissues where it may be euchromatic. This phenomenon was demonstrated in the grasshopper *Melanoplus*, in spermatocytes, the *X* chromosome is heterochromatic at prophase, and replicates its DNA later than the autosomes[2,52]. The same chromosome is, however, euchromatic or slightly negatively heteropycnotic in the spermatogonia, and in this tissue the incorporation of tritiated thymidine takes place at the same time as in the autosomes[53].

This result is most significant in demonstrating that it is invalid to study the autoradiographic picture of a given chromosome in a tissue where this chromosome is not known with accuracy to be heterochromatic, and from such a result we draw conclusions about the relation between heterochromatin and the sequence of DNA replication.

In *Microtus oregoni* Hsu *et al* [54] described results which they believed contradicted the rule of chromosome replication. In this species Ohno *et al* [55] had observed a large chromocenter in embryonic liver cells which they interpreted as representing two-thirds of the *X* chromosome seen at prophase. Hsu *et al* did not administer tritiated thymidine to this tissue but to lung fibroblasts grown *in vitro*, in which they then studied DNA replication at metaphase, when heterochromatin is invisible. They did not find late replication of the segments presumed to be heterochromatic at interphase in the liver, and they concluded that this case represented a departure from the relation between late replication and heterochromatin. Autoradiography was carried out in one tissue and heterochromatin was observed in another, and therefore such an experiment cannot be used as an example in establishing the relation between late replication and heterochromatin.

It is not a corollary of our DNA rule that any chromosome or chromosome region which is late replicating should be heterochromatic. Thus within the chromosomes of various species different regions replicate at different times showing no indication of being heterochromatic. When heterochromatin is not present, other factors, not yet apparent, determine the sequence of replication of various segments within and between chromosomes[57].

It can be stated at present that what determines the presence of heterochromatin also determines the late replication of a chromosome, or, in other words, what changes the condensation cycle of the chromosome at the same time shifts its timing of DNA replication. What determines the late replication of a chromosome or chromosome region, however, may not necessarily determine the onset of heterochromatin.

It should be noted that heterochromatin was originally discovered by its expression at the chromosome phenotype, and it is still primarily recognized by the changes which occur at this level. What happens at the gene level or at the molecular level of chromosome organization, when heterochromatin becomes apparent at the microscopic level—a jump from the Angstrom to the micron level—is unknown. The synthesis of *m*RNA in heterochromatin and in euchromatin, as well as the role of histones in the repression of this synthesis, is now being studied[60–63] and these results may give clues which will allow us to put the microscopic and molecular information into a coherent framework.

Structure and Distribution of Glycosyl Diglycerides in Bacteria

by

N. SHAW

J. BADDILEY

Microbiological Chemistry Research Laboratory,
Department of Organic Chemistry,
University of Newcastle upon Tyne

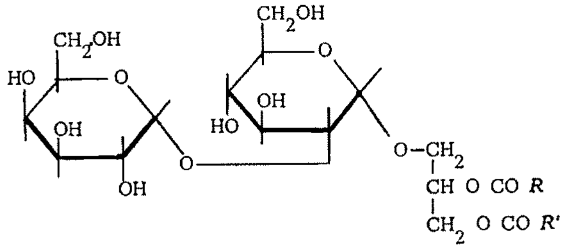
Glycosyl diglycerides are widely distributed in Gram-positive bacteria. Those examined so far contain only glucose, galactose or mannose, and they can be classified according to the nature of the disaccharide attached to their diglyceride component. This chemical classification can be related to general bacterial taxonomy.

THE recognition of the metabolic and structural importance of lipids has led to increased interest in them and in particular bacterial lipids. The wealth of information available on the phosphatide and fatty acid composition of numerous bacteria has enabled certain phylogenetic relationships to be established and this subject has been extensively reviewed[1,2]. New types of lipids have been discovered, and two of the most interesting recent developments have been the recognition of the widespread occurrence of the amino-acid esters of phosphatidyl glycerol[3] and the glycosyl diglycerides[4]. The structure, function and distribution of glycosyl diglycerides in bacteria have been studied in a number of laboratories, and this article reviews certain structural features and relationships that are emerging from this work.

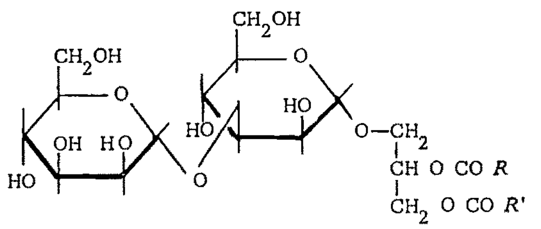
With the exception of extensive investigations by Lederer and his associates on the glycolipids of mycobacteria[5], no information was available on the structure and distribution of glycolipids in other bacteria until, in 1961, Macfarlane reported the presence of a mannosyl diglyceride in *Micrococcus lysodeikticus*[6]. The following year Polonovski, Wald and Paysant-Diament isolated a diglucosyl diglyceride from *Staphylococcus aureus*[7], although in neither case was the full structure determined. Our interest in this field developed from the observation that the lipids of a *Pneumococcus* Type I contained considerable quantities of 1-[*O*-α-D-galactopyranosyl-(1→2)-*O*-α-D-glucopyranosyl]-2,3-diglyceride (Fig 1)[8]. Independently, Kaufman, Kundig, Distler and Roseman proposed an identical structure for the glycolipid from *Pneumococcus* Type XIV (ref 9). Several Gram-positive bacteria were then examined and the presence of similar compounds was established in all of them[4]. More recently, many other bacteria have been shown to possess this type of lipid, the widespread distribution of which is firmly established. From these studies, summarized in Table 1, certain tentative conclusions may be drawn concerning their structure and distribution.

The principal glycolipid in nearly all the organisms shown in Table 1 is a diglycosyl diglyceride. This type of lipid, first discovered in plants[10], is composed of a disaccharide residue glycosidically linked to the 1-position of an α β-diglyceride. Five groups have so far been recognized, depending on the nature of the disaccharide, these are the α-glucosylglucosyl, β-glucoslyglucosyl, α-galactosylglucosyl, β-galactosylgalactosyl and α-mannosylmannosyl diglycerides. Within each group the complete structure of at least one member has been determined and is shown in Fig 1. In four of the groups where structure determinations have been carried out on several members (indicated by an asterisk in Table 1), the diglycosylglycerols produced by hydrolysis of the glycolipids with alkali have identical structures within each group. Glucose, galactose and mannose are the only sugars found so far in these glycolipids and, of the five types of diglycosylglycerols, four contain disaccharides of a single hexose. The two anomeric centres in the glycosides have the same configuration and, in the four glycosides containing glucose or galactose or both, an α-linked disaccharide contains a 1→2 linkage between the two sugar residues whereas a β-linked disaccharide has a 1→6 linkage.

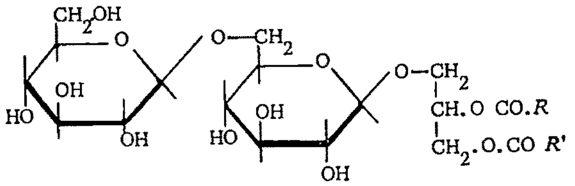
The glycolipids yield a single glycoside on hydrolysis with alkali, with the exception of those from *Arthrobacter globiformis*, where both a dimannosyl and a digalactosyl diglyceride occur together This organism is known to exist in two morphological forms[11] and it is possible that these two forms each contain a single but different diglycosyl diglyceride. Polonovski *et al* have reported[12] that the glycoside from *Staphylococcus aureus* is a mixture of two isomeric diglucosylglycerols containing respectively a 1→6 and a 1→3 linkage between the two sugars, but their evidence is inconclusive and has not been confirmed in our studies on *S. aureus*. Biosynthetic studies have shown that in *Micrococcus lysodeikticus*[13] and *Pneumococcus* Type XIV (ref 9), a monoglycosyl diglyceride is the immediate biosynthetic precursor of the diglycosyl diglyceride and it is probable that this mechanism of biosynthesis is usual In only three organisms, however, has a significant amount of a monoglycosyl diglyceride been detected Furthermore, in two of these organisms, *Arthrobacter globiformis* and *Mycoplasma laidlawii B*, a diglycosyl diglyceride is also present and the relative amounts of these two components will presumably depend on culture conditions and the growth phase at the time of isolation Small quantities of triglycosyl diglyceride have been detected in several lactobacilli and *Streptococcus faecalis*, and in *Lactobacillus plantarum* 17–5 it is the sole glycolipid component Gas–liquid chromatographic studies on the fatty acid composition of the glycolipids have shown a similar distribution to that in the other lipids



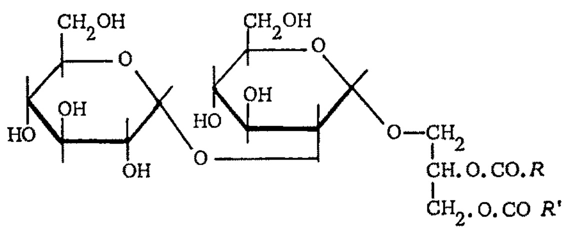
1-[*O*-α-D-galactopyranosyl-(1→2)-*O*-α-D-glucopyranosyl]-2,3-diglyceride



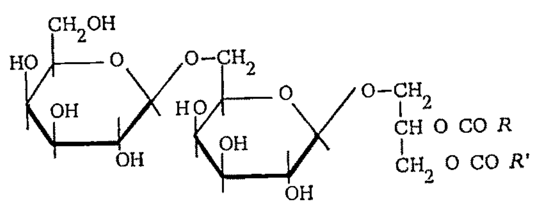
1-[*O*-α-D-mannopyranosyl-(1→3)-*O*-α-D-mannopyranosyl]-2,3-diglyceride



1-[*O*-β-D-glucopyranosyl-(1→6)-*O*-β-D-glucopyranosyl]-2,3-diglyceride



1-[*O*-α-D-glucopyranosyl-(1→2)-*O*-α-D-glucopyranosyl]-2,3-diglyceride



1-[*O*-β-D-galactopyranosyl-(1→6)-*O*-β-D-galactopyranosyl]-2,3-diglyceride

* Complete structure has been determined.

† The organisms listed contain these glycolipids as principal components Small quantities have been observed in other organisms

Two conclusions may be drawn from a study of the distribution of these glycolipids. First, they have only been isolated from Gram-positive bacteria and, second, significant relationships concerning the nature of the glycolipid present and the taxonomy of the organisms are being revealed Although an extensive survey of Gram-negative bacteria has not been carried out, none of those examined in detail (Table 1) contained glycosyl diglycerides It would be premature to claim their universal occurrence in Gram-positive bacteria, but the presence of a glycosyl diglyceride has been shown in all such organisms examined in these laboratories. Their presence in the mycoplasma, a group of organisms lacking the normal rigid bacterial cell wall, is especially interesting and adds further support to the similarities which have already been established between the mycoplasma and the L-forms of Gram-positive bacteria[14]

The distribution of the five groups of diglycosyl diglycerides shows that the galactosylglucosyl diglycerides are found in the lactobacilli and two strains of pneumococcus, the α-glucosylglucosyl diglycerides are found in streptococci and *Mycoplasma laidlawii B*, the β-glucosylglucosyl diglycerides are found in staphylococci and *Bacillus subtilis* and the dimannosyl diglycerides are found in *Micrococcus lysodeikticus* and the closely related organisms *Arthrobacter globiformis* and *Microbacterium lacticum* Thus while the same glycolipid can be found in organisms belonging to different families, members of the same genus or closely related species contain identical glycolipids

Quantitative studies have shown that the amount of glycolipid is variable, ranging from a few per cent of the total lipid in the lactobacilli and staphylococci to more than 40 per cent in *Microbacterium lacticum* and *Mycoplasma laidlawii B* Until more evidence is obtained concerning the function of these compounds and their rate of accumulation and turnover in the organism, it is difficult to draw any useful conclusions from these figures In common with the phosphatides of Gram-positive bacteria, their location in the membrane has been firmly established in several instances[15–17]

There is still no evidence to support earlier suggestions[18] that these glycolipids might be concerned in the transfer of sugar residues from nucleoside diphosphate sugars to polysaccharide chains, although the occurrence of the larger compounds would be consistent with such a function More recent events, however, have made this less likely because it has been shown that in the biosynthesis of lipopolysaccharides[19] and peptidoglycans[20] sugar residues are attached to an intermediate lipid pyrophosphate in which the lipid is a polyisoprenoid alcohol, a phospholipid intermediate has also been demonstrated in the biosynthesis of a teichoic acid (L J Douglas, N. L. Blumsom and J Baddiley, unpublished work) An alternative function has been suggested by Brundish, Shaw and Baddiley[21] from an examination of the shape of diglycosyl diglycerides These glycolipids can adopt a conformation in which all the hydroxyl groups lie on one side of the molecule and the lipophilic components (fatty acids, ring oxygen of sugars and glycosidic oxygens) lie on the other side The hydrophilic regions of a number of molecules could come together to form a "pore" in the membrane through which small ions and water-soluble metabolites could pass

The conclusions presented here are based on a study of relatively few organisms and consequently may be invalidated by further work in this field In our view, however, the results obtained so far are sufficiently encouraging to suggest that this approach will complement the results of phosphatide and fatty acid analysis in the study of phylogenetic relationships in bacteria

Measurement of an Antigen–Antibody Reaction by a Static Method utilizing a Porous Gel

by

CLAUDE SOULEIL
ALFRED NISONOFF

Department of Microbiology,
University of Illinois College of Medicine,
Chicago, Illinois

Using radioactively labelled markers of high and low molecular weight, as well as radioactive ligand, it has been shown that binding of antibody to hen egg lysozyme is nearly complete.

THE availability of cross-linked dextrans or polyacrylamide gels of varying pore size ('Sephadex', 'Bio-Gel') has led to their use in the quantitative estimation of interactions between a protein and a small molecule, between protein molecules or protein subunits Such interactions have usually been measured by using columns of the gel[1–5] A static method, which is less time consuming and which more readily permits measurements in a steady state, was described by Fasella *et al*[6] In applying the method to an antigen–antibody interaction we have encountered difficulties resulting from non-specific adsorption to the gel of protein which is present at low concentrations By using radioactively labelled markers of high and low molecular weight, as well as radioactive ligand, we have been able to detect small amounts of non-specific adsorption and to evaluate unlabelled carriers for their ability to reduce non-specific adsorption by displacement of the adsorbed ligand Also, such markers provide reference points which allow direct calculation of the extent of binding The system which has been investi-

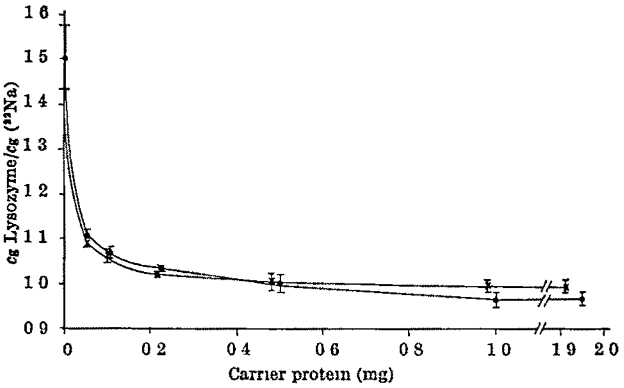

Fig 1 Effect of unlabelled carrier protein on the ratio, c_g (iodine-125-lysozyme)/c_g (sodium-22) ● Unlabelled horse heart cytochrome *c* added as the carrier ×, Unlabelled lysozyme as carrier Total volume, 4 6 ml Other details are in the text Experiments in triplicate with standard deviations indicated by the bars

gated is the combination of hen egg lysozyme (molecular weight, 14,600) with its rabbit antibody (molecular weight, 150,000) The method should, however, have general applicability

'Bio-Gel *P*-60', 100–200 mesh, was obtained from the Bio-Rad Company and was allowed to swell in a buffer containing 0 15 molar sodium chloride and 0 003 molar sodium borate, *p*H 8 Crystallized lysozyme was obtained from the Mann Research Laboratories The extinction coefficient, $E_{1\text{ cm}}^{1\text{ per cent}}$ at 280 mμ, was taken as 26 (ref 7) Lysozyme and non-specific rabbit γG-immunoglobulin (IgG) were labelled with iodine-125 and iodine-131, respectively (0 5 to 2 0 atoms of iodine/molecule of protein[8]) Unreacted iodine was removed by gel filtration or by dialysis More than 99 per cent of the radioactivity in each preparation could be precipitated by 5 per cent trichloroacetic acid, with unlabelled bovine IgG present as a carrier Sodium-22 chloride was obtained from the Nuclear Chicago Company

Equilibration of protein solution with the gel was carried out in a 5 ml vial with a screw cap and a polyvinyl chloride–polyvinyl acetate gasket In most experiments, 2 5 ml of solution and approximately 2 g of a suspension of swollen beads were placed in the vial which was then cooled in an ice-bath The system was equilibrated by inverting the vial ten times and allowing the beads to settle after each inversion Control experiments showed that five or six inversions were sufficient for equilibration The mixture was transferred to a weighed test tube which was used for gamma counting The supernatant was completely removed with a very fine pipette, transferred to another tube and weighed Radioactivities of the beads and supernatant were measured in a 3-channel 'Packard' gamma scintillation counter The radioactivity which was determined for each isotope was corrected for the contributions, at the window settings used, by the other isotopes present in the mixture A minimum of five thousand counts above background was recorded in each channel

An experimental parameter which is useful in discussing these data is the concentration of an isotope within the gel suspension after equilibration, relative to its concentration in the supernatant fluid This value, which we designate c_g, depends on the volume within the pores of the gel which is accessible to the isotope, on the spaces between the beads (void volume) and on the amount of material, if any, which is adsorbed to the gel Experimentally, c_g is evaluated by determining the net radioactivity/g of supernatant solution (A) and the radioactivity/g of the suspension of beads (B), c_g is the ratio B/A

In preliminary experiments, c_g was determined for sodium-22 in solutions of sodium-22 chloride having approximately 1,000 counts/min/ml, but in which total concentrations of sodium chloride varied (0 01, 0 05, 0 1, 0 15, 0 2 and 0 3 molar); the corresponding values of c_g were 0 96, 0 97, 0 96, 0 95, 0 94 and 0 96. The constancy of c_g with increasing concentration suggests that the fraction of sodium which is non-specifically bound to the beads is not significant at the concentrations which were tested Further evidence comes from a comparison of c_g (sodium-22) with the weight of buffer in 1 g of a suspension of 'Bio-Gel *P*-60' This weight was found to be 0 946 g, in close agreement with the average value of c_g

A mixture was prepared in triplicate at *p*H 8 containing 0 15 molar sodium-22 chloride, 0 003 molar sodium borate and iodine-125-lysozyme at a final concentration of 0 022 μg/ml The average ratio, c_g (lysozyme)/c_g (sodium), was 1 50 and quite variable (Fig 1, ordinate intercept) suggesting non-specific adsorption of lysozyme to the gel When unlabelled lysozyme was added as carrier in increasing amounts, this ratio decreased and approached a constant value close to unity (Fig. 1) This constancy and the close agreement between the values for sodium and lysozyme suggest that the fraction of lysozyme which is non-specifically adsorbed becomes negligible as the total concentration of carrier increases above 0 1 mg/ml

For studying interactions with rabbit antilysozyme, however, such concentrations are not very practical because, at equivalence, the weight ratio of antibody to lysozyme is about 14 1, so that large amounts of antibody would be needed Also, it is essential to use very low concentrations of lysozyme to avoid formation of precipitates during the half-hour period before removal of supernatant from the gel When the concentration of lysozyme used is less than 1 μg/ml, no turbidity is observed in control experiments during this time interval

Another basic protein, horse heart cytochrome c (Sigma Chemical Co), was found to be equally as good as unlabelled lysozyme in reducing non-specific adsorption (Fig 1) Precipitin data for lysozyme and its rabbit antibody in the presence and absence of added cytochrome c are shown in Fig 2 The data show that the

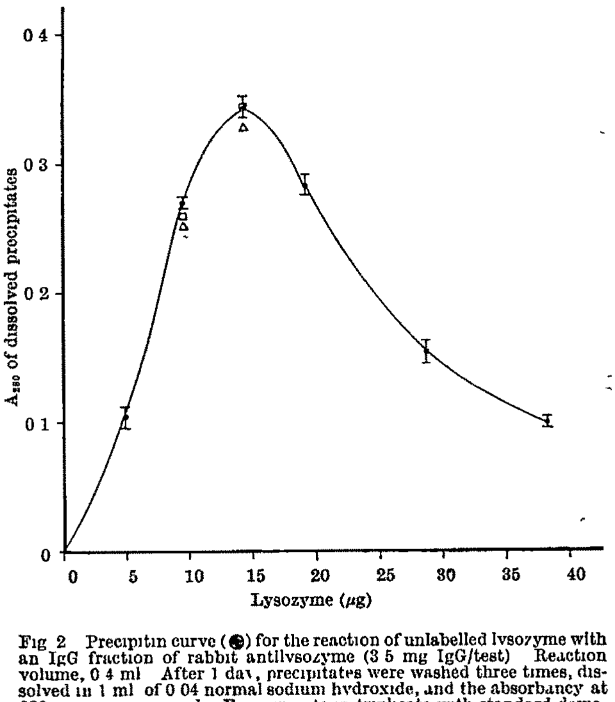

Fig 2 Precipitin curve (●) for the reaction of unlabelled lysozyme with an IgG fraction of rabbit antilysozyme (3 5 mg IgG/test) Reaction volume, 0 4 ml After 1 day, precipitates were washed three times, dissolved in 1 ml of 0 04 normal sodium hydroxide, and the absorbancy at 280 mμ was measured Experiments in triplicate with standard deviations indicated by the bars Two experiments (△) were repeated in duplicate in the presence of 1 mg of horse heart cytochrome *c*, and two (□) with iodine-125-lysozyme in place of the unlabelled protein The average mean deviation for the experiments with labelled iodine-125-lysozyme or with cytochrome *c* present was 0 010 units of absorbance

cytochrome *c* does not compete with lysozyme for antibody combining sites, it was therefore used as carrier in subsequent experiments.

Rabbit iodine-131-IgG (molecular weight, 150,000) was used as an indicator which is excluded from 'Bio-Gel *P*-60'. The value of c_g (IgG) was found to be 0·48 ± 0·015 and was essentially independent of concentration in the range which was investigated (0·02 to 3·5 mg/ml).

Fig. 3 shows the effect of addition of antilysozyme (IgG) to a mixture at *p*H 8 containing 0·15 molar sodium-22 chloride, 0·003 molar borate, non-specific iodine-131-IgG (0·46 mg), iodine-125-lysozyme (0·1 μg) and cytochrome *c* (1 mg). The total volume, including 2·6 g of bead suspension, was approximately 4·6 ml. With increasing concentrations of antilysozyme the ratio, c_g (lysozyme)/c_g (sodium-22), decreased from 0·95 to 0·55. At the same time the ratio, c_g (lysozyme)/c_g (iodine-131-IgG), decreased from 1·94 to 1·05 (Fig. 3). The close agreement between c_g of non-specific IgG and that of the lysozyme–antibody complex is consistent with the interpretation that both are excluded from the pores of 'Bio-Gel *P*-60' and that essentially all of the lysozyme is bound when an excess of antibody is present. That the binding is nearly complete is supported by other data, described later.

It can be shown that in the absence of non-specific adsorption a linear relationship should exist between the fraction of lysozyme which is bound to antibody and c_g (lysozyme). On this basis, the amount of antibody (IgG fraction) required to bind 50 per cent of the 0·1 μg of lysozyme present is estimated, from the data of Fig. 3, to be 10·2 μg. On the assumption that all of the antibody and antigen are precipitated at equivalence (Fig. 2), 10·2 μg of antibody globulin contains 0·60 μg of antibody. On this basis the ratio, moles of antibody present/moles of lysozyme bound, was 1·4 when 50 per cent was bound.

To check the results by an independent method, complexes of lysozyme and antibody were precipitated with sheep antiserum. Varying amounts of antilysozyme (IgG) and non-specific IgG were mixed to give a total of 0·2 mg of protein in a volume of 1·6 ml. of borate buffer, *p*H 8. Iodine-125-lysozyme (0·05 μg in 0·05 ml.) was added, followed after 10 min by 0·4 ml. of sheep antiserum of high titre which was prepared against the heavy chains of rabbit IgG. In preliminary experiments with iodine-131–rabbit IgG, 92 per cent of the iodine-131 was precipitated in these conditions. In two experiments, 1 mg of horse cytochrome *c* was present. The concentration of lysozyme was chosen so as to be very similar to the concentration outside the gel in the experiments of Fig. 3, at the point corresponding to 50 per cent binding.

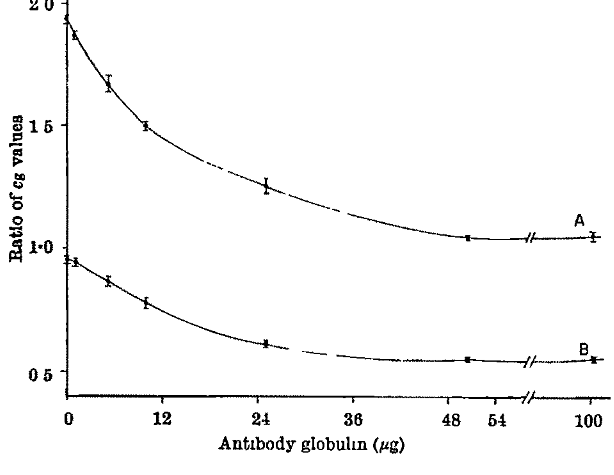

Fig. 3. Effect of added antibody (IgG fraction) on the ratio, c_g (iodine-125-lysozyme)/c_g (iodine-131-IgG) (curve *A*), or c_g (iodine-125-lysozyme)/c_g (sodium-22) (curve *B*). Details are in the text. Experiments in triplicate with standard deviations indicated by bars.

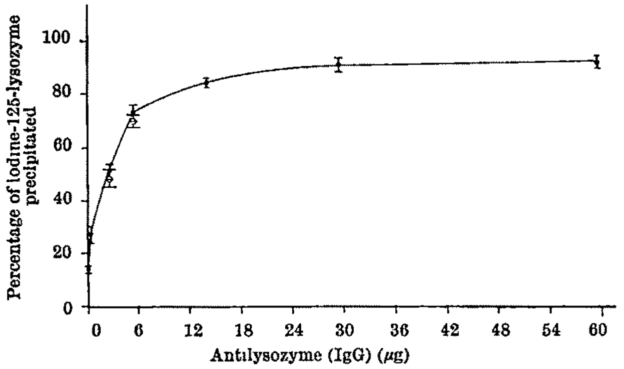

Fig. 4. Indirect precipitation of complexes of iodine-125-lysozyme and rabbit antilysozyme (IgG fraction) by sheep antiserum to H chains of rabbit IgG. Mixtures contained 0·05 μg iodine-125-lysozyme, an amount of the antilysozyme shown on the graph, and 0·4 ml. of the sheep antiserum. In two experiments (open circles), 1 mg cytochrome *c* was also present. Reaction volume, 2 ml. Experiments in triplicate with standard deviations indicated by bars.

After standing for 1 day in the refrigerator, each precipitate was separated by centrifugation, washed three times and the total radioactivities in the combined supernatant fluids and in the dissolved precipitate were measured.

The results (Fig. 4) show that the amount of antibody globulin which is needed to react with half of the antigen (0·025 μg) is 3·1 μg. In making this computation the amount of antigen which is non-specifically precipitated in the absence of antibody (0·006 μg, ordinate intercept of Fig. 4) was subtracted from each value on the curve. The amount of antibody globulin required to bind 0·05 μg is therefore 6·2 μg, as compared with the value 10·2 μg which was derived from experiments using the gel (Fig. 3). The reason for the disparity is not apparent, but in view of the difference in conditions and reagents in the two sets of experiments the agreement seems reasonably close.

The difficulties which were encountered should be mentioned. One is the binding of lysozyme to non-specific IgG, which becomes appreciable at globulin concentrations above 2 mg/ml. Also, the binding of lysozyme to glass is significant at low concentrations in the absence of carrier protein. In experiments with another batch of 'Bio-Gel *P*-60', lysozyme was not completely included within the pores of the gel, which suggests that the pore size of 'Bio-Gel *P*-60' does not greatly exceed the size of lysozyme molecules. This, however, may be attributable to partial dimerization of the protein[7]. The precision of the method is poor when a small percentage of ligand is bound, because the magnitude of the experimental variation of c_g then approaches the differences between c_g of the ligand and c_g of the internal control (sodium-22). The experimental variation, expressed as fraction of ligand bound, is about 5 per cent when half is bound.

The method is useful for showing the binding capacity of an antibody or other protein and, if components of sufficiently high specific radioactivity are used, should permit determination of dilutions at which dissociation of two reacting proteins occurs, and thus their association constant.

Spiral Structure and Galactic Magnetic Field

THE amount of data available on the magnetic field of the Galaxy has increased considerably since the discovery of linear polarization in the galactic background radio emission[1] There now exist three different methods for determining the structure of the field, these being (1) optical observations of interstellar polarization, (2) Faraday rotation measures of extra-galactic radio sources, and (3) the polarization of the galactic radio emission

The chief conclusions drawn from the data are summarized in Table 1 The distances given in the penultimate column are in most cases estimated from the dimensions of the region in which the particular effect is supposed to take place In some cases, the distances have been estimated by those doing the analysis or the observations

Table 1

Method	Direction of the field	Region of the Galaxy	Distance from the Sun	Ref
Interstellar polarization	$l=50°$	In plane of the Galaxy	~ 600 parsec	12
" "	$l=45°$	Along spiral arm	0–1,000 parsec	10
" "	$l=40°$–$45°$	In plane of the Galaxy	60–260 parsec	2
Radio background polarization	$l=50°$	In local spiral arm	~ 150 parsec	4
" " "	$l=70°$	" " "	~ 150 parsec	13
" " "	$l=50°$	" " "	> 110 parsec	2
" " "	$l\sim70°$	Beyond spiral arm	> 500 parsec	2
Faraday rotation measures of extra-galactic radio sources	$l=95°$	In plane of the Galaxy	~ 600 parsec	6
" " "	$l=95°$	Below galactic plane	~ 600 parsec	6
" " "	$l=275°$	Above galactic plane	~ 600 parsec	6
" " "	$l=80°$	In plane of the Galaxy	~ 600 parsec	14
" " "	$l=80°$	Below galactic plane	~ 600 parsec	14
" " "	$l=260°$	Above galactic plane	~ 600 parsec	14
" " "	$l=91°$	In plane of the Galaxy	> 1,100 parsec	2
" " "	$l=82°$	Below galactic plane	> 1,100 parsec	2
" " "	$l=260°$	Above galactic plane	> 1,100 parsec	2

Using the method I described earlier[2], I carried out a spherical harmonic analysis of the interstellar polarization data of Behr[3], and I carried out a similar analysis on the radio background polarization data of Berkhuijsen *et al*[4] and the data of Bingham[5] I also used the data of Gardner and Davies[6] for a spherical harmonic analysis of rotation measures From these analyses I deduced the direction of the field in different regions of the Galaxy

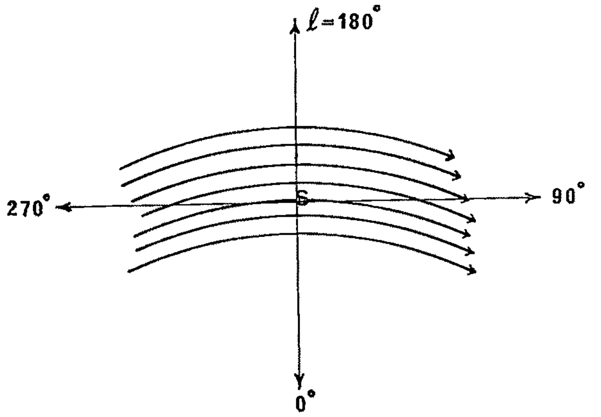

Fig 1 The large scale structure of the magnetic field deduced from Faraday rotation observations The angles give the galactic longitude, and *S* represents the position of the Sun

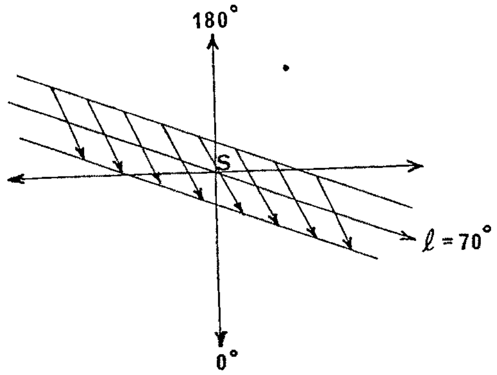

Fig 2 The lines parallel to $l=70°$ represent the local spiral arm The lines across the arm represent the field deduced from optical and radio polarization measurements

Recently, two models have been proposed which attempt to account for all the available observations In the first model, Hornby[7] suggested that the magnetic field in the local spiral arm has a form very similar to that of a tightly wound helix Stepien[8] had already shown that some forms of helices were consistent with the interstellar polarization data Hornby showed that his model made possible an explanation of the field reversal seen at intermediate latitudes He also showed that the model was able to explain the principal features of the background polarization data His model, however, is unable to explain the direction of the field in the plane of the Galaxy

Bingham and Shakeshaft[9] considered a model in which the magnetic field in the plane of the Galaxy converged towards the direction $l=70°$ Their model was able to explain some aspects of the interstellar polarization data It is not, however, consistent with the data in the direction $l=75°$ (see ref 10) Their model also included a magnetic loop above the plane With this loop, they were able to explain the field reversal above the plane Like Hornby, they ignored certain low latitude sources on the grounds that the Faraday rotation for these sources takes place beyond the local spiral arm As a result, their model is unable to explain the direction of the field in the plane of the Galaxy They show that their model is consistent with the background polarization data

I have shown[2] that a toroidal field in the plane of the Galaxy was able to explain the Faraday rotation data, if one assumed that the Faraday rotation was not confined to the local spiral arm I also showed that a simple radial component was not consistent with the data. Faraday rotation thus gives a field of the form shown in Fig 1 Optical polarization together with the polarization of the radio background emission, however, gives us a field of the form shown in Fig 2

Lin and Shu[11] suggested that the spiral arms are regions of high density in a wavelike pattern which covers the disk of the Galaxy. This pattern is formed by periodic displacements of stars and gas parallel to the galactic plane. These displacements are caused by motions caused by gravitational effects In such a theory the spiral arms, as well as any segment of a line parallel to them, are lines of equal phase These periodic motions would distort a simple toroidal field because the field is probably frozen into the interstellar matter If the field lines are not to cross each other, if they are to remain connected and if there are no large scale twists about axes parallel to the galactic plane, then there are only a few possible configurations for the field lines to take Let us represent the local spiral arm by the curve *AB* (see Fig 3) and a section of the local magnetic field by the curve *ab* Consider two points *c* and *d* chosen in such a way that *c* lies on a line of equal phase that lags, say, π behind *AB*, and *d* lies on a similar line that

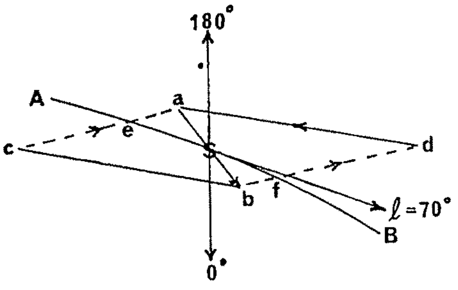

Fig 3. A schematic representation of possible ways of joining the local field to the large scale field (see text)

leads AB by π Thus c and d are 2π out of phase There are two ways of joining a and b to c and d Suppose we join d to a and b to c If we now follow the curve $dabc$ we move in a direction of steadily increasing phase all along the curve Thus this curve represents a configuration which could be obtained from the periodic disturbances. The curve, however, gives us a field that points from d to a and from b to c This is not consistent with the Faraday rotation measures of extra-galactic radio sources The other possibility is to join c to a and b to d In this case, the curve would cut the local spiral arm in points e and f as well as S (the position of the Sun) The field at e and f is in a direction differing from that at S. The field direction is therefore not uniquely defined by the phase, and this is impossible on our assumptions Thus such a situation could not arise from the type of motion we described earlier

A general toroidal field cannot be distorted by periodic disturbances, confined to the plane of the Galaxy, to give rise to the local spiral arm field, if the field lines are to remain connected and are not to cross each other This leads us to suppose that there may also be systematic motions perpendicular to the galactic plane or that the field lines in the spiral arms are not connected to the general galactic field

I should like to thank Professor F D Kahn for many helpful discussions

New Restriction on Models for Quasi-stellar Objects

THE inverse Compton effect has recently received attention as a possible source of the continuous radiation of quasi-stellar objects[1-3] Hoyle *et al* [4] concluded that quasi-stellar objects cannot be at cosmological distances because otherwise the inverse Compton effect would force the electrons to dump their relativistic energies in times so short that no known acceleration mechanism could be responsible for their original appearance Modifications of this argument have been discussed by several authors[5-9], in particular by Woltjer[10], who considered a radiation (and electron) flux restricted to a narrow cone about the radial direction

In all these discussions, only the spontaneous component of the Compton effect was considered There is also, however, a stimulated term which is a straightforward consequence of quantum mechanics and which was recognized as such as early as 1933 by Kapitza and Dirac[11] It is the purpose of this communication to show that the—necessary—inclusion of the stimulated processes makes an understanding of the radiation pattern of quasi-stellar objects in terms of currently proposed models extremely difficult

We assume that there are relativistic electrons moving through a radiation field Let their energy be such that, in familiar notation, $\gamma=[1-\beta^2]^{-1/2}\gg 1$, where $v=\beta c$ is the electron speed in the observer's frame Furthermore, let the energy ε of the photons in the observer's frame be such that $\varepsilon'\sim\gamma\varepsilon\ll\mu$, where ε' is the photon energy in the rest frame of the electron, $\mu=m_0c^2$ the rest energy of the electrons Finally, let θ be the angle between the photon and electron paths in the observer's frame, so that a photon travelling parallel to the direction of motion of the electron from behind corresponds to $\theta=0$ In the rest frame of the electron, however, all but the few photons arriving with $0\leqq\gamma^{-1}$ will seem to arrive with $\theta'\sim\pi$, so that $\cos(\chi'+\theta_i')\sim-\cos\chi'$, where χ' is the scattering angle in the electron frame

The probability of a Compton process is now proportional to $[1+n(\varepsilon)]$, where

$$n(\varepsilon)=[(\pi\hbar c)^3/\pi\varepsilon^2]\,N(\varepsilon) \qquad (1)$$

and $N(\varepsilon)$ is the number of photons of energy ε per cm³, $2\pi\hbar$ being Planck's constant and c the speed of light $n(\varepsilon)$ is an invariant, so that $n'(\varepsilon',\theta')=n(\varepsilon,\theta)$ The power generated through Compton scattering can then be written as[12]

$$\begin{aligned}4\pi P_c=2\pi^2r_0{}^2\int\sin\chi'\,d\chi'\int\sin\theta_i\,d\theta_i\,(1+\cos^2\chi')\,(1-\beta\cos\theta_i)\\ \times\{\gamma^2(1-\beta\cos\theta_i)\,[1-\beta\cos\chi']-1\}\\ \times\int d\varepsilon_i\,c\,\varepsilon_i\,N(\varepsilon_i)\,[1+n(\varepsilon_f)]\end{aligned} \qquad (2)$$

In equation (2) we have taken the Thomson approximation to the Klein–Nishina cross-section θ_i and θ_i', in the respective reference frames, are the angles of the incoming photon (energy ε_i in the observer's frame); ε_f is the energy of the outgoing photon

It may suffice to derive a lower bound of the energy transferred from the electrons to the radiation field This we can obtain by rather simple considerations, a detailed analysis will appear elsewhere To arrive at such an estimate, we first consider scattering angles $\chi'>1/\alpha$, where $\alpha<\gamma$ Almost all events in this domain lead to an increase in the photon energy, whereas scatterings with $\chi'<1/\alpha$ will be essentially symmetric in energy gain or loss Thus, if we extend the integration over χ' from $\cos\chi'=-1$ to $\cos\chi'=1-1/2\alpha^2$ only, we are certain to collect energy gains The detailed calculation shows that $4\alpha^2\sim\ln\gamma^2$ Similarly, we restrict the integration over θ_i to the $\cos\theta_i$ range between -1 and $1-1/2\gamma^2$ With the total flux $F=\int cN(\varepsilon)\varepsilon d\varepsilon$ we find for the spontaneous component

$$4\pi P_c^{sp}=4\pi\,(32\pi/9)\,\gamma^2\,r_0{}^2\,F \qquad (3)$$

Writing $\cos\chi'=x$, $\cos\theta_i=y$, the stimulated component reads

$$\begin{aligned}4\pi P_c^{st}=2\pi^2r_0{}^2\int dx\int dy\,(1+x^2)\,(1-\beta y)\,\{\gamma^2(1-\beta y)\\ \times\,(1-\beta x)-1\}\int d\varepsilon_i\,F(\varepsilon_i)\,\pi^2h^3c^2\varepsilon_f{}^{-3}\,F(\varepsilon_f)\end{aligned} \qquad (4)$$

Initial and final energies are related by $\varepsilon_f=\varepsilon_i\,\gamma^2\,(1-\beta y)\times(1-\beta x)$

In order to proceed, we have to choose a specific flux spectrum. We first consider the case of constant flux, introducing boundaries $\varepsilon_1=h\nu_1$ and $\varepsilon_2=h\nu_2$ at which we cut off the spectrum In addition, for the stimulated term, we must ascertain that both initial and final photon energies lie within the flux boundaries This amounts to limiting the ε integration between $\varepsilon_i = \varepsilon_1$ and $\varepsilon_f = \varepsilon_2$, or between $\varepsilon_i = \varepsilon_1$ and $\varepsilon_i = \varepsilon_2/\gamma^2\,(1-\beta y)\,(1-\beta x)$ The integrations lead to the result

$$4\pi P_c^{st} = 4\pi\,\frac{[\ln(2\gamma^2)]^2}{32\gamma^4}\,r_0^2\,(c^2/h)\,\frac{F^2}{\nu_1^2\nu_2^2} \qquad (5)$$

The total flux F is about $F(\varepsilon)$ ε_2 Taking $\gamma^2 \sim 10^2$ in the logarithm, we find the ratio

$$R_1 = P_c^{st}/P_c^{sp} = 3\ 7\times10^{46}\,\frac{F_0Q^2}{\gamma^6\nu_1^2\nu_2^2} \qquad (6)$$

Here we introduced the flux F_0 at Earth distance, Q being the ratio of the distance between Earth and quasi-stellar object and the radius of the quasi-stellar object

Similarly, the power spectrum for a monochromatic flux with index −1 (ref 13, Table 5 1) yields

$$4\pi P_c^{st} = 4\pi\,(3/64)\,\gamma^{-4}\,r_0^2\,(c^2/h)\,\frac{F_0Q^2}{[\ln(\nu_2/\nu_1)]^2\nu_1^4} \qquad (7)$$

The expression corresponding to equation (6) now reads

$$R_2 = P_c^{st}/P_c^{sp} = 6\ 1\times10^{44}\,\frac{F_0Q^2}{\gamma^6[\ln(\nu_2/\nu_1)]^2\nu_1^4} \qquad (8)$$

Finally, the calculation for Woltjer's model[10] shows that, although the spontaneous component is significantly reduced, the stimulated component is very nearly the same as in the isotropic case, provided that photons and electrons are not aligned to within an angle of order $1/\gamma$

It is worth emphasizing that equations (6) and (8) refer to monochromatic electrons But because the γ dependence is very strong and with a negative exponent, the implication is that in a continuous energy distribution the slowest electrons lose their energy first, so that in effect we have a lower limit for the electron energies in a stationary situation

If we insert the values (compatible with *3C* 273) $F_0 = 10^{-8}$, $\gamma = 10^2$, $\nu_1 = 10^7$, $\nu_2 = 10^{13}$, r (quasi-stellar object) $= 10^{17}$, d (quasi-stellar object) $= 10^{27}$ (cosmological distance) so that $Q^2 = 10^{20}$ (all units in CGS), we find $R_1 = 3\ 7\times10^6$ If we adopt the local hypothesis for quasi-stellar objects the numerical value of R_1 is reduced by roughly a factor 10^4 As already mentioned, Hoyle *et al*[4], from considering the spontaneous component, concluded that the electrons in quasi-stellar objects could survive, if the sources were not at cosmological distances Adding the stimulated component seems to preclude even this possibility, at least for electrons with $\gamma \sim 10^2$ to 10^3 The reduction in lifetime is even more drastic for a flux spectrum $F(\varepsilon) \sim \varepsilon^{-1}$, namely, $R_2 = 2\ 7\times10^{14}$ for the same values of F_0

Thus, and regardless as to whether we adopt the local or the cosmological hypothesis, we are left with two choices

(1) The radiation field of quasi-stellar objects is caused by electrons supplied *in situ* or, at any rate, not accelerated anywhere near the locus of the radiation field The electrons at the low energy end of the spectrum are then decelerated "instantaneously", feeding the radiation field by means of stimulated Compton effect It is interesting to speculate that if this mechanism were operating, the radiation field would be made to align itself more and more with any preferred direction of particle motion If the particle motion is highly anisotropic, for example, purely radial, and if the radiation field has reached a state of confinement to a cone about the direction of particle motion of half-angle γ^{-1}, the stimulated scattering mechanism ceases to be efficient At this time, the low energy portion of the photon spectrum may have been seriously depleted This effect could obviously be cited as an explanation for the observed curvature of the spectrum of many quasi-stellar objects

(2) The alternative is for the radiation field to be produced by a mechanism that does not involve relativistic electrons

PLANETARY SCIENCE

Incoming Solar Radiation over the Tropical Pacific

THERE seems to be a much larger amount of total incoming solar radiation (direct and diffuse radiation on a horizontal surface as recorded by the Eppley pyranometer) at the ocean surface over the equatorial Pacific—and probably over much of the tropical Pacific as a whole—than has usually been thought It also seems that the incoming solar radiation over the central and western parts of the equatorial Pacific dry zone would closely approach the extremely large amounts received over the tropical and subtropical desert areas of the continents These statements are based on a study of recorded incoming solar radiation data for Wake and Canton Islands in relation to associated cloud distributions and also on comparisons of the long-term Canton Island cloud distribution with that of several other small islands in the central and western equatorial Pacific (Both Wake and Canton seem to be reasonably representative marine sites by virtue of their small land areas, lack of relief and complete isolation from continental influence)

The recent global illustrations by Budyko[1] show upward revisions of the incoming solar radiation over the tropical Pacific when compared with his[2,3] earlier depictions and the works of Kimball[4] and Black[5], but they are still not indicative of the recorded incoming solar radiation values at Wake and Canton Islands For example, Budyko's 1963[1] representation of the average annual solar radiation reception at both these sites would indicate values slightly in excess of 160 kLangleys* Wake Island, however, shows an average annual reception of 194 kLangleys[6], based on a 9 year period of record, and the average annual figure for Canton Island is 218 kLangleys[7], based on a 12 year period of record Why do such large differences occur ?

There is an extreme lack of solar radiation recording stations over the tropical Pacific, and it is apparent that computed values for incoming solar radiation, based on cloud cover data from the much more numerous weather observing sites, have had a controlling influence on the tropical Pacific representation Computations based on meteorological data usually consider only mean total sky cover, and most of the formulae in use were developed originally for middle latitude conditions where cloud distributions and solar altitude ranges are quite different from those of the tropics Even during the highly unusual meteorological period July 1957 to June 1958, when Canton received 82 22 in of rainfall (usual annual precipitation

* One Langley is 1 cal cm⁻² min⁻¹

Table 1 AVERAGE TRANSMISSION PERCENTAGES FOR DESIGNATED SOLAR ALTITUDE RANGES IN STIPULATED SKY COVER CONDITIONS

Coverage (in tenths)	Solar altitude ranges 0°–14°	15°–29°	30°–44°	45°–59°	60°–74°	75°–90°	Average
<2 0 TC	46 9 (5)	65 6 (10)	73 2 (10)	76 6 (12)	77 8 (17)	77 6 (5)	69 6 (Pertains essentially to clear sky)
10 0 TC and <2 0 TOC	45 3 (36)	63 9 (24)	72 3 (24)	76 1 (26)	76 8 (26)	77 4 (6)	68 6 (Pertains essentially to cirriform overcast)

TC, total sky cover, TOC, total opaque sky cover. Figures in parentheses refer to the number of cases in the particular category

29 43 in) and had 9 0 tenths average total sky cover (mean annual sky cover 6 3 tenths), it received approximately 195 kLangleys

It seems quite significant that a 43 per cent increase in mean annual sky cover only caused an 11 per cent reduction from the average annual incoming solar radiation for Canton (The 11 per cent figure is based on approximately eleven months of data, because all radiation data for February 1958 were missing If, however, the missing data were available, it is difficult to see how the annual reduction would be increased beyond 12 per cent) The explanation of this situation seems to lie in the cloud distribution by type and amount During the period July 1957 to June 1958, Canton experienced 10 0 tenths thin cirriform clouds with scattered or no low clouds about 40 per cent of the time This percentage is very high but would, of course, be much higher if specifications were changed so as to include the same low cloud criteria (scattered or none) and all cirriform ceilings (that is, 6 to 10 tenths cirrus or cirrostratus) This thin cirriform cloud cover, which was the principal contributor to total sky cover during fair weather, apparently had very little effect on the incoming solar radiation Even during this year of relatively high precipitation and cloud cover, the percentage of time with disturbed weather and its associated heavy opaque cloud cover and precipitation was relatively small when compared with the percentage of time during which fair weather prevailed

To ascertain the reduction in radiation caused by thin cirriform clouds alone, it was first necessary to determine the incoming solar radiation during clear sky conditions at Canton There were so few clear hours from July 1957 to June 1958 that it was necessary to consider all observations with less than 2 0 tenths total sky cover, after eliminating those situations when there were obviously low cloud patches directly between the pyranometer and the Sun (This was accomplished by a study of the Canton Island radiation traces for each hour involved Large, short period downward displacements in the radiation trace were indicative of the periods when low cloud patches were above the pyranometer) To obtain incoming solar radiation when just the cirriform overcast was present, those hours with 10 0 tenths cirrostratus or cirrus and less than 2 0 tenths total opaque sky cover were used, following the same procedure to eliminate cases where a low cloud patch was directly between the pyranometer and the Sun (The opaque sky cover in these fair weather situations ordinarily pertains to low cloud patches) Table 1 contains average transmission percentages for the incoming solar radiation within the various solar altitude ranges (The individual transmission percentages, which were used to arrive at the average values of Table 1, were obtained by dividing the recorded hourly incoming solar radiation at the surface by the computed hourly incoming solar radiation at the top of the atmosphere, and then multiplying the result by 100) Figures in this table indicate that the thin cirriform overcast did not cause a significant reduction of the incoming solar radiation regardless of solar altitude The general decrease in transmission percentage with decrease in solar altitude, which affected both categories similarly, was caused by the increase in air mass penetrated at the lower solar altitudes For the long period record (a 209 month US Air Force Air Weather Service uniform summary of surface weather observations for Canton Island), although the mean cloud amounts show a considerable reduction from the amounts recorded for the July 1957 to June 1958 period, a similar cloud distribution is shown with high clouds as the important contributor to total sky cover

The incoming solar radiation pattern over the tropical Pacific is likely to resemble that shown by Wyrtki[8], in that a tropical minimum reception would be expected along the zone most frequently occupied by the intertropical convergence zone of the northern hemisphere, and a maximum would be expected in the equatorial dry zone The incoming solar radiation amounts, however, would seem to be considerably higher At Wake Island's location (19° 17′ N, 166° 39′ E) Wyrtki's chart gives about 165 kLangleys/yr (recorded average about 194 kLangleys/yr) and at Canton's location (2° 46′ S, 171° 43′ W) his chart also indicates about 165 kLangleys/yr (recorded average about 218 kLangleys) Wyrtki's incoming solar radiation figures exclude that part of the solar radiation reflected from the ocean surface, but, because this only amounts to about 6 to 7 per cent of the total incoming solar radiation, it cannot account for the large differences between the observed and computed values

If Canton Island, during this year of unusually large average total sky cover (9 0 tenths) and heavy rainfall (82 22 in), recorded about 195 kLangleys of incoming solar radiation, there must be a very large portion of the tropical Pacific receiving annually in excess of 180 kLangleys and a sizable portion receiving in excess of 200 kLangleys It is expected that the maximum annual reception over the Pacific would occur in the central and western portions of the equatorial dry zone where values may reach 200 kLangleys or more The large cirriform contribution to total sky cover seems to have prevented earlier recognition of this situation In those cases where a balance has been achieved, using the computed solar radiation figures, compensating errors most probably occur in one or more of the remaining heat budget terms

This work was supported by grants from the US National Science Foundation and the US Office of Naval Research We thank Mrs S A Kulm and Mrs S J Borden for their assistance in computing the hourly solar radiation received on a horizontal surface at the top of the atmosphere

Semi-annual Variation in Thermospheric Density

KING-HELE[1] has reported a semi-annual variation in thermospheric density at about 190 km with a maximum to minimum ratio of 1 45 Cook's hypothesis[2] that the semi-annual variation is caused by the modulation of the helium content of the lower thermosphere, originally coined to account for the variation at 1,100 km, clearly cannot be applied to explain changes at 190 km. The reconciliation between theory and observation is in essentially the same state as it was a year ago There is the hypothesis of Anderson[3] that the semi-annual variation results from a migration of the perigee points of the satellites studied with latitude in such a manner that the drag at perigee is small when over the winter pole which is supposed to be cold (and of lower density than the equatorial regions) Debate is continuing about Anderson's hypothesis[4,5] and no doubt the issue can be resolved when sufficient values of density for a wide range of perigee latitudes and over all seasons are available, such as the simultaneous changes at 190 and 1,100 km Anderson quotes as support my colleagues' computations[6], which show a cold winter pole The influence of motions, however, was neglected in these computations and it has recently been shown that the influence of vertical motions is quite substantial (ref 7 and unpublished work of R E Dickinson, C P Lagos and R E Newell) Satellite drag observations by Jacchia[8] and Keating and Prior[9] show higher densities over the winter pole than over the summer pole Jacchia and Slowey[10] could reduce —but not eliminate—the effect by manipulating parameters in their model, indeed, the effect was predicted before observation[11] and seems to increase with altitude as expected from theory

Another suggestion[12] is that the modulation of extreme ultraviolet radiation is responsible for the semi-annual change, just as it is responsible for the changes in the densities during the 27 day and solar cycles Unfortunately, while there may have been an association between extreme ultraviolet and density in 1962–63, there seems to have been density changes[13] without changes in the extreme ultraviolet in several other years

Density changes are observed at 190 km and may be caused by pressure change at some lower level or by temperature changes within the 100–190 km layer (if the influence of changes in composition is ignored at these altitudes) At 80 km there is an annual density and pressure variation with a maxima in summer in the region[14] 30°–60° N. The question is what other mechanisms are available to produce temperature changes in the 100–200 km layer? Johnson (see Jacchia[13]) has proposed large-scale meridional motions which subtract more heat from the region during the solstice than during the equinoxes, thereby producing a semi-annual density variation Another possibility would seem to be that Joule heating associated with ionospheric currents has a semi-annual variation Such heating has been considered by many authors (see Cole[15]) Both disturbance currents, caused by magnetic storms and usually measured by K_p, and steady currents denoted as S_q, have maxima at the equinoxes King-Hele has attempted to eliminate large variations in K_p from his results by omitting nineteen large storms in the period His elimination criterion is not stated but seems to be about $K_p \leqslant 5_0$ from inspection of the data There are very few days with very low K_p, 74 days out of 386 have $K_p \leqslant 2^-$ Radio aurora can sometimes be observed when $K_p = 2$, and by implication Joule heating will be associated with the ionospheric currents, at least in polar regions It is clearly difficult to assess the heating effect of many small disturbances, but it is well known that K_p shows equinoctal peaks It has been suggested that the peaks result from leakage of energy from the large scale waves in the lower atmosphere into the thermosphere[16] The transmission between tropopause and mesopause is a maximum near the equinoxes when the winds are changing from westerly to easterly or vice versa.

The quiet day currents are also at a maximum near the equinoxes[17] and it is possible that vertical fluxes associated with tidal motions can penetrate into the lower thermosphere at these times when the prevailing zonal winds at 100 km are also close to zero in middle latitudes[18] There is some (slight) experimental evidence that the diurnal tide does seem to pepetrate more easily at these times[19]. The amplitudes of the S_q currents are largest over the equator and if a typical equinoctal current is taken as 4×10^5 amp (I) per 60° of latitude spanning the equator, and an average column conductivity (σ) between 100 and 120 km is taken as 10 mho (ignoring the complications introduced by the tensor nature of conductivity), then the Joule heating (I^2/σ) is 0 36 erg cm^{-2} sec^{-1} For a typical winter current of 3×10^5 amp the corresponding heating is 0 21 erg cm^{-2} sec^{-1}

What is the temperature change in the 100 to 120 km region necessary to account for an observed density change of about 1 4 at 180 km, if all other parameters including the temperature between 120 and 180 km are kept constant? An estimate from the hydrostatic equation and the equation of state using 10 km increments in height gives a value of about 40° K for the mean increase in temperature necessary in the 100–120 km layer In turn an energy flux of about 0 1 erg cm^{-2} sec^{-1} acting for 10 days is implied, the danger of such simple estimates is obvious because composition, temperature gradient and downward heat flux will all change concomitantly, but nevertheless the fact is that the small Joule heating inferred from the currents can be significant in altering the density of the 180 km level Small changes in K_p, when $K_p < 5$ are also associated with substantial current changes as measured in terms of the numbers already mentioned, although these changes are largest at high latitudes Similarly, the larger change in Joule heating associated with K_p storm events may account for the observed density changes associated with K_p (ref 20) and the differences between day and night currents may also be important in the observed diurnal changes[21]. In so far as the S_q currents are thought to be driven by atmospheric motions and some K_p changes may also be driven from below, King-Hele's report may be treated as additional experimental evidence for a leakage hypothesis A test of all these items, including Johnson's proposal of meridional motion, could be made by comparing the results from a global network of meteor wind stations, as proposed elsewhere[19], with thermospheric densities

Stable Lead in Fossil Ice and Bones

DURING the past hundred years about 1×10^{14} g of lead has been dispersed by man in the biosphere[1], and the question arises as to whether this has increased the exposure of modern societies to chronic lead intoxication The chief sources of lead in the atmosphere are the combustion of petrol and coal and the contributions from both these sources are now of the same order of magnitude although in the past the greater contribution was from coal[2] In effect, the existing concentrations of lead in different components of the biosphere are now much higher than the natural concentrations which have been calculated[3] To investigate the temporal variations in the lead content of the environment and in the human body I have collected samples of glacial ice representing the precipitations of the past hundred years, and also samples of human bones covering the period from the third to the twentieth centuries In these samples lead was determined by dithizone colorimetry according to the method described earlier[4]

Ice samples were collected from a miniature corrie glacier in the Great Mieguszowiecki Cirque and from a glacier in the cave Grota Lodowa in the Tatra Mountains Both localities have already been described[5] As Fig 1 shows, the mean concentration of lead in the ice has increased steadily during the past hundred years The mean concentration which has been found in contemporary samples (1960–65) of 75 µg/l. was about sixteen times greater than that in the oldest samples from about 1861–66, in which the mean concentration was 5 0 µg/l These results are similar to the data of Murozumi *et al* [6], who found that the concentration of lead in the Greenland snow dating from 1905 was sixteen times lower than in the snow of 1964 The low concentrations of lead during 1861–1966 are probably not the natural concentrations, because in that time the precipitations could have been polluted by industrial activity in the neighbouring Silesian centres It is surprising that the increasing concentrations of lead in the ice are similar to the increasing annual use of coal as a source of energy[7] This correlation is not necessarily exclusively caused by the volatilization of the lead in fuel combustion, but it is probably connected with the increase in general industrial activity, related to the rate of coal burning

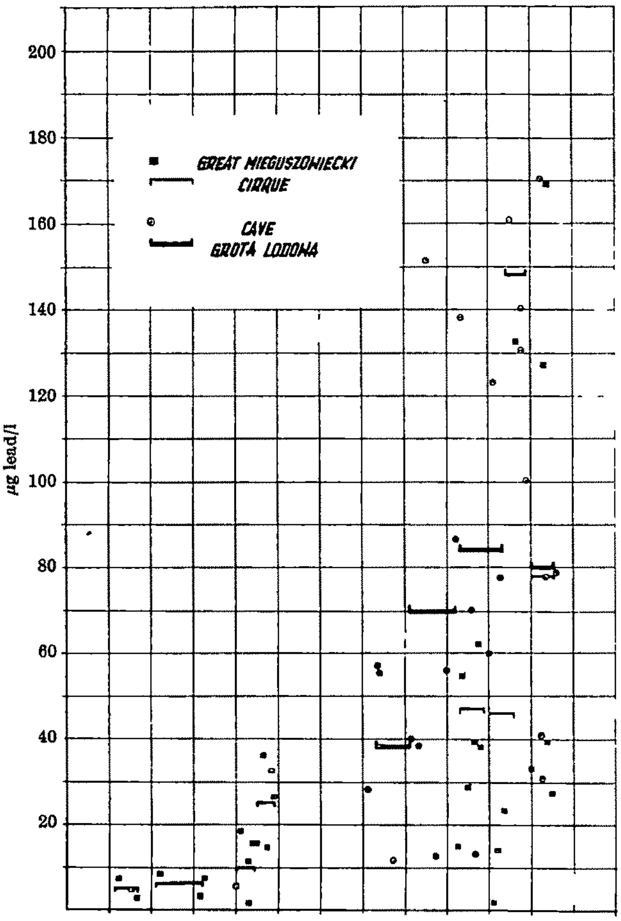

Fig. 1 Concentrations of stable lead in the glacier ice Lines represent the mean concentrations for a period

The samples of human bones were collected in four churches in Cracow and its region Most of them were preserved in wooden or stone coffins which were stored in dry underground crypts, although some bones from the Tyniec Monastery (samples 7–12) were buried directly in the loess beneath the central part of the church The third century bones were collected in a limestone cave near Kroczyce in the province of Katowice, where the skeletons were found lying on the dry stony floor Samples 1 and 2 from this cave were collected in 1936, immediately after the cave was discovered, and samples 3, 4 and 5 were collected in 1967 The latter samples could have been contaminated by visitors

Table 1 CONCENTRATION OF STABLE LEAD IN HUMAN FOSSIL BONES

Recent (mean of 20 samples)		Poland	3 9	Vertebrae

As can be seen from Table 1, the low concentrations of lead in the third century bones contrast with the high lead content of the bones from the eleventh to the nineteenth centuries The unusually high concentration of lead in the bones of an individual from the thirteenth century (skeleton No 8) was in all probability acquired during life, because relatively low concentrations of lead were found in other skeletons from the same locality which were buried 1 to 2 metres away from skeleton 8 The high concentrations of lead in the bones of humans living in Poland between the eleventh and nineteenth centuries are similar to the concentrations which were observed in contemporary bones in the United Kingdom. Germany and the United States[8-12] On the other hand the lead contents of the bones of contemporary residents of Poland are lower than they were in the past, although the contamination of the environment with lead, as reflected by the concentration of lead in the fossil precipitations, has increased during the past hundred years This suggests that in Poland the contribution from the atmosphere to the level of lead in the population is now smaller than the contribution from other sources in the past These sources were probably tin kitchen utensils which were widely used, and which contained large proportions of lead[13,14] It can also be supposed that the high head content in the bones of contemporary residents of western countries is probably caused not by pollution of the atmosphere resulting from industrial activity, but rather by dietary habits and contamination of food

The low lead concentrations which were found in the third century bones of 1 81 and 1 84 µg/g of dried bone are remarkably near the value of 0 85 µg/g, which was theoretically estimated to be the natural concentration[3] According to T Dabrowska (private communication) the third century inhabitants of Poland probably had no contact with metallic lead, and it can be supposed that their bones show the natural concentration of lead, which is about 1–2 µg/g of dry bone

I thank the Metropolitan Curia of Warsaw, the Diocesa Curia of Cracow and Professor Kazimierz Kowalski for help in collecting the bone samples I was greatly helped by the encouragement and support of the late Professor Edward Kowalski This work was supported in part by the International Atomic Energy Agency

Variations in *Pc* 1 Frequency with Latitude

Recordings of the magnetic micropulsations called *Pc* 1 from two auroral zone stations, College, Alaska, and Sodankyla, Finland (64 6° N and 63 8° N. geomagnetic, respectively), and one subauroral station, Nurmijaarvi, Finland (57 8° N), show a marked latitude variation in mid-frequency of structured *Pc* 1 events Analysis of data for a 3 month period (Table 1) shows that the average frequency of structured *Pc* 1 at Nurmijaarvi, the lower latitude station, is significantly higher than that for the auroral zone stations Fig. 1 shows a 6 Hz *Pc* 1 event which was recorded at Nurmijaarvi

Table 1 AVERAGE *Pc* 1 FREQUENCIES (HZ) OF THE HALF-HOURLY OCCURRENCES IN 1967

	January	May	June
Nurmijaarvi	1 32	2 39	1 95
Sodankyla		0 79	0 96
College	0 72	0 74	0 57

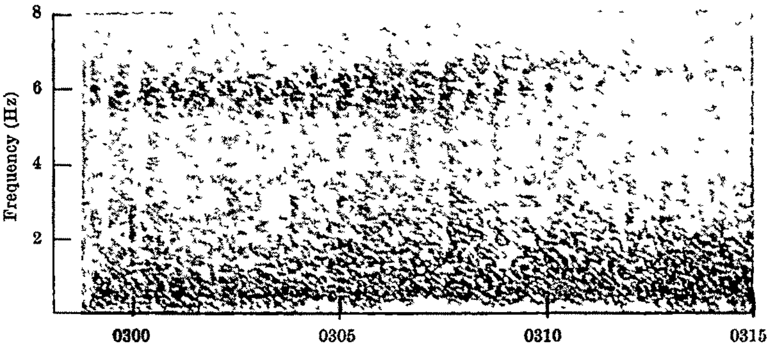

Fig 1 Sonagram showing very high frequency structured *Pc* 1 event, Nurmijaarvi, Finland June 7, 1967

There is considerable evidence that structured *Pc* 1 originate within the magnetosphere on "closed" field lines[1-5] Satellite observations have shown that the closed field lines extend to approximately 75° geomagnetic latitude on the day side and to 69° on the night side during magnetically quiet times, with the boundaries tending to move towards the equator with increasing *Kp* (ref 6) The location of the sources of *Pc* 1 within this region remains to be determined Furthermore, the existence of a latitude-frequency relationship within this *Pc* 1 source region is important, because some theoretical mechanisms involve the ion gyroresonance instabilities[7-9], and the ion gyrofrequency increases inwards in the magnetosphere's equatorial plane Some other mechanisms, for example, "hydromagnetic whistlers"[9], do not require this latitude variation in source frequency if a simple broad-band initiating impulse is postulated

The mid-frequencies for each of the three stations for June are presented in a diurnal variation display (Fig 2) The "occurrences" are half-hour intervals which contain structured *Pc* 1 activity Note that during the midday hours all of the Nurmijaarvi occurrences were above 1 1 Hz, whereas at Sodankyla and College all occurrences were $\leqslant$1 1 Hz

A complication which arises here from the fact that it is possible for Sodankyla to be outside the "closed" field line region on some occasions of high *Kp*, while Nurmijaarvi is inside Thus if *Pc* 1 do tend to occur in the outer part of the "closed" line region, then events would tend to be recorded at Nurmijaarvi at times of higher *Kp* than at Sodankyla, and the apparent latitude variation in *Pc* 1 frequency could be caused instead by the changing level of magnetic activity We averaged the *Kp* indices for times of the *Pc* 1 occurrences for May and for June For the College occurrences *Kp* averaged 1 95 and 1 91, and for Sodankyla 1 77 and 1 74, but for Nurmijaarvi the averages were 2 65 and 2 40 Thus in these data the more southerly station tended to experience structured *Pc* 1 at times of higher *Kp* To remove the effect of variations in *Kp* we deleted Nurmijaarvi *Pc* 1 occurrences from the May data for times when $Kp > 2^+$ The remaining *Kp* then averaged 1 63 and the average *Pc* 1 mid-frequency was 2 03 Hz Similarly, for June, the restriction $Kp \leqslant 3-$ brought the Nurmijaarvi average *Pc* 1 frequency down to 1 77 Hz, still well above the Sodankyla average frequency From these and other results it seems that variations in *Kp* cannot fully account for the observed *Pc* 1 frequency-latitude variations

Structured *Pc* 1 events recorded at one of the Finland stations in the summer months were usually not received at the other, in spite of a separation in latitude of only 6° For example, of the forty-six and sixty-five occurrences in May 1967 at Nurmijaarvi and Sodankyla, respectively

(Fig. 3), only three were simultaneous, with appearance of similar frequency-time on both records.

In Fig 2 there is a wide spread in frequencies for night-time occurrences. This suggests that propagation across field lines, north and south from the source lines, may be best at night, and thus that a station receives signals from a wider range of latitudes at night This idea is consistent with the fact that California receives *Pc* 1 signals essentially only at night[10] This further suggests that propagation across field lines should be best in winter months To check this, we analysed the data for January 1967 There was a remarkable number of occurrences at Nurmijaarvi and at College—343 and 124, respectively. In contrast, in May and June the occurrences/month/station averaged approximately seventy The average *Pc* 1 frequencies for January (Table 1) were more nearly equal at the two stations as compared with the summer data Also, the average *Kp* values for *Pc* 1 occurrences were nearly equal in January These results are seen to be consistent with the idea that the *Pc* 1 signals propagate best across field lines at night and in winter Thus it seems that the latitude spread in *Pc* 1 frequencies is most reliably studied by using daytime and summer data We note again from Fig 3 that at midday all Nurmijaarvi occurrences were >1·1 Hz and all College and Sodankyla occurrences were <1·1 Hz

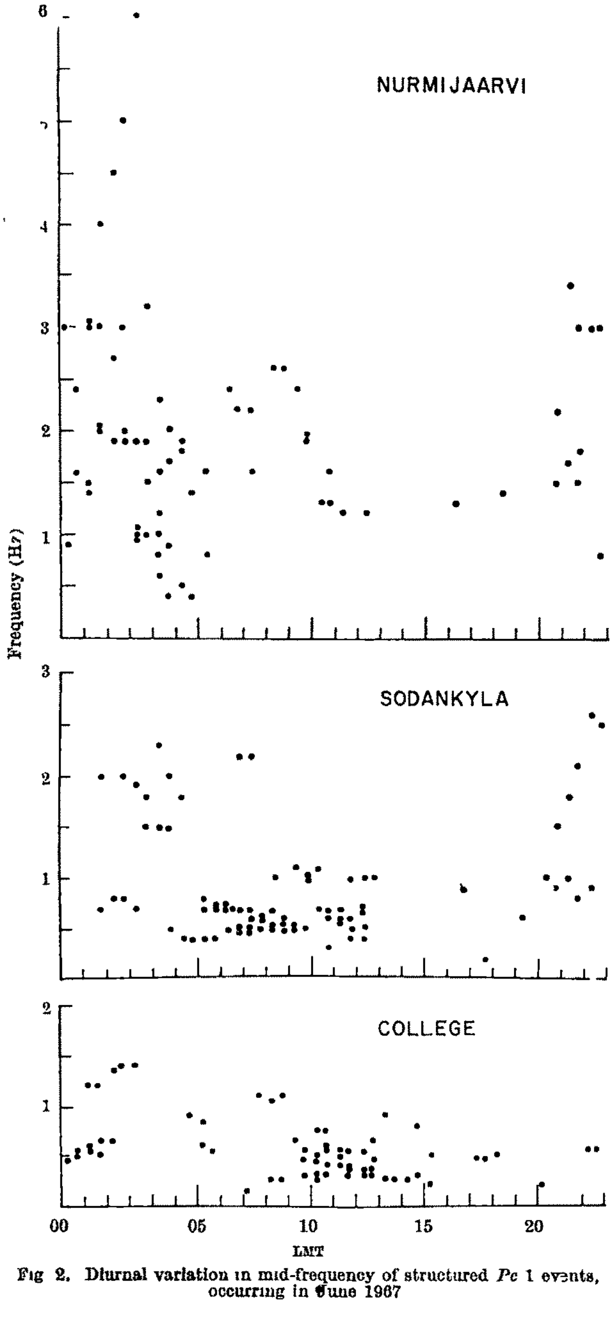

Fig 2. Diurnal variation in mid-frequency of structured *Pc* 1 events, occurring in June 1967

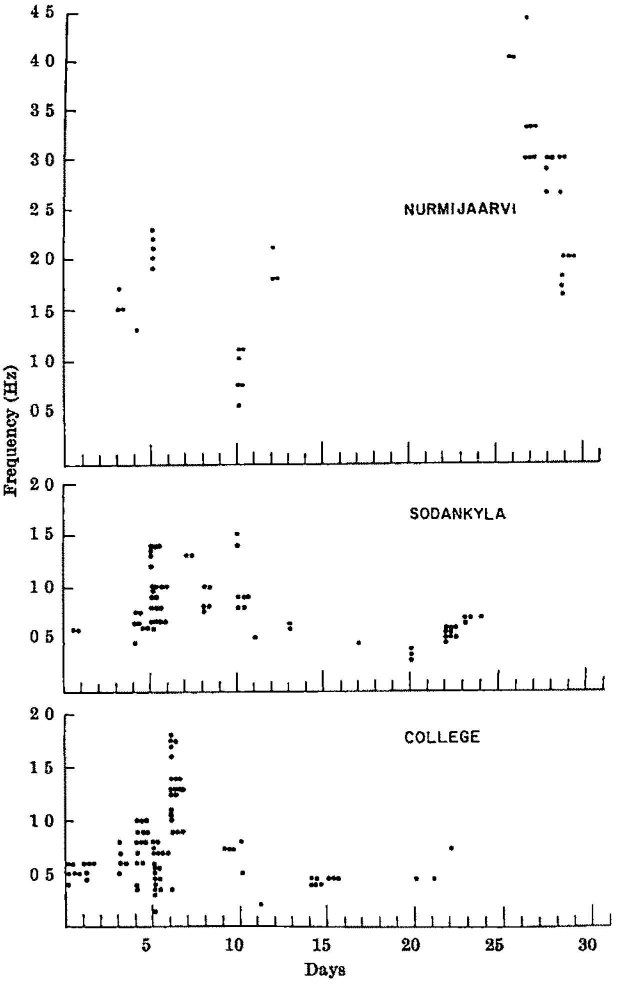

Fig 3 Mid-frequency of all structured *Pc* 1 events recorded at Nurmijaarvi, Sodankyla and College, May 1967

Theoretical works show that the higher frequencies are damped more heavily in the ionosphere[11] We therefore expect that if Nurmijaarvi is located near the source field lines for the higher *Pc* 1 frequencies, then stations at lower latitudes may record lower average *Pc* 1 frequencies than Nurmijaarvi, because of the attenuation of the highs in an ionospheric duct during southward propagation of the signal Tepley and Wentworth[12] recorded *Pc* 1 with average frequency near 1 Hz at Palo Alto, at about 40° N

There are certainly possible explanations for the *Pc* 1 frequency variation other than the latitude variation in equatorial proton gyrofrequency For example, there could be latitude variations in the magnitudes of certain wave damping mechanisms in the ionosphere and exosphere, and there could be more than one type of ion involved with a latitude spread in the distribution of the types. Dowden[13] has suggested that helium atoms as well as protons are involved in *Pc* 1 generation At present, however, there is no evidence for the existence of either of those latitude variations

The results presented here do seem to favour the *Pc* 1 theories which depend on the ion gyroresonance mechanism[7–9], and present difficulties for certain other mechanisms

Origin of the Newgale Shingle Embankment, St. Bride's Bay, Pembrokeshire

MANY of the shingle accumulations round the coastline of Britain pose problems of origin because there is no apparent source of supply for them One such accumulation is that at Newgale in Pembrokeshire (Fig 1), a study of which has provided evidence relating both to the source of supply of the shingle and to the reasons for its concentration This evidence may be of general interest with regard to the problem of explaining how such banks originate

St Bride's Bay is highly irregular in plan, the bay-head consisting of several small beaches separated by headlands The only substantial accumulation of shingle is at Newgale, where an embankment 17 ft high extends for 1 25 miles Steers[1] has suggested that "Along the northern shore of St Bride's Bay beach material travels eastward and the storm beach at Newgale thus accumulates, at least in part" This view attempts to explain both the origin and concentration of the shingle By his further assertion that "It (the embankment) is formed of stones of local origin"[1], Steers seems to imply that cliff erosion and the alongshore transport of the debris are principally responsible for the embankment The difficulties with this suggestion are first that there are erratics present, and second, it is doubtful whether shingle could move along the northern shore because of the minor headlands, which would obstruct movement, even with a lower sea level

To explain the presence of flint shingle on the coast of southern England far from possible sources, Hardy[2] developed an idea of Steers[3] in which a rising post-glacial sea level is envisaged "sweeping up" shingle in front of it This hypothesis would seem applicable at Newgale The presence of erratics restricts the provenance of the shingle, at least in part, to drift Such deposits do not exist on land near Newgale, and so it is suggested that the source of the erratics is drift on the bay floor As a rising sea level "sweeping up" erratics from the drift would also remove stones of local origin, the drift could be the direct source of most of the embankment's shingle. It is therefore unnecessary to infer movement along the northern shore

Steers's hypothesis of littoral movement attempted to explain the origin and concentration of the shingle The rising sea level theory solves only the former problem With reference to the latter, Hardy has suggested that in southern England[2] and Norfolk[4] shingle structures are associated with areas of concentrated constructive wave energy An attempt has been made to test this idea at Newgale

The principal directions of wave approach to St Bride's Bay lie in the south western quadrant Wave refraction diagrams of the Arthur, Munk and Isaacs type[5] drawn for various directions within this quadrant for periods between 3 and 10 sec show that energy levels increase generally northwards along the bay-head, which is to be expected because of the sheltering effect of the southern headland Maximum energy is therefore associated with the shingle accumulation, although the association is not confined to long constructive waves Hardy's view is that this association of shingle with concentrations of constructive energy can be explained in that the sorting of shingle to produce a beach is achieved largely by constructive waves, so that any concentration of these will lead to a shingle concentration Hardy's work is concerned with beaches built from loose shingle on the sea bed and not from chalk *in situ* The removal of stones from drift would require a concentration of shorter, steeper, destructive waves before the building of an embankment by longer, less steep, constructive waves It is considered significant that waves of several lengths show maximum energy levels at Newgale

There is thus at Newgale an association of high energy values with a shingle accumulation For a causal relationship to be inferred it must be shown that a similar concentration of energy existed during the post-glacial rise in sea level The isobaths (Fig. 1) demonstrate that the bay form would have been in existence throughout this rise, so that the shelter effect of the southern headland would be a dominant factor controlling the energy distribution patterns at successive coastlines Maximum energy levels throughout the rise would therefore be in

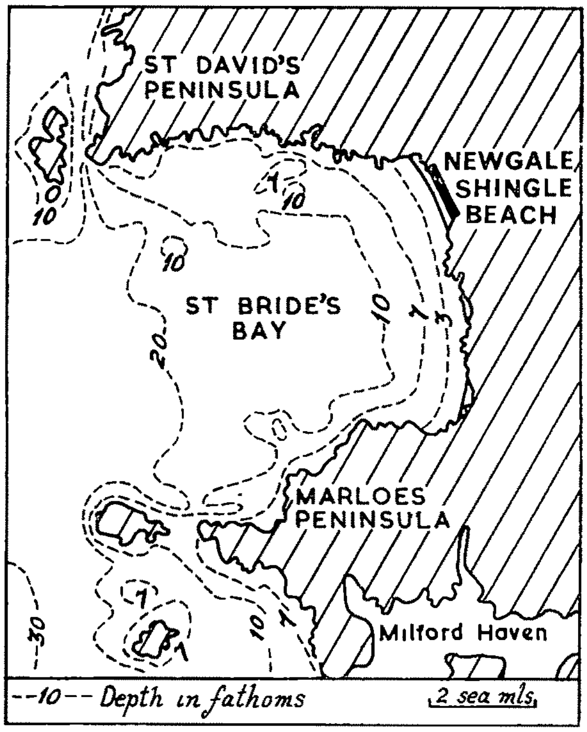

Fig 1 St Bride's Bay

the northern part of the bay. In addition, each successive bay shape would be relatively more inset, resulting in a progressive intensification of the shelter effect, which would in turn result in a tendency for the alongshore energy differential to become more pronounced with time.

I think that the Newgale embankment is composed largely of drift derived shingle from the bay floor and that the reason for its location is that wave energy has been continuously concentrated in the northern part of the bay. The postulated causal relationship between concentrated wave energy and shingle accumulation gains support from this investigation.

Theoretical Model for the Chandler Wobble*

EULER is usually credited with having been the first to show that an axially symmetric rigid body, with a fractional difference between the equatorial and polar moments of inertia equal to that of the Earth, could undergo a free nutation with a period of about 300 days. That is, in a body-fixed co-ordinate system, the instantaneous axis of rotation would describe a cone about the polar axis with a 300 day period. It could have been expected that such a motion, even if present primordially, would have been damped almost completely by natural dissipative processes within the Earth. Such a motion would show itself in a periodic variation in astronomic latitude of a given site on the Earth's surface, because the rotation axis moves only slightly with respect to an inertial frame[1]. Despite the expectance of almost complete damping, repeated attempts were made in the nineteenth century to uncover indications of a variation in latitude with a 10 month period. None was definitely established, but in 1891 Chandler[2] announced a variation with a period of 428 days, about 40 per cent larger than predicted. Newcomb soon realized that the period of free nutation for the Earth would be greater than the rigid-body value, because of the fluid nature of the oceans and elastic yielding of the solid earth, and he proposed that Chandler's observations were indeed of the free nutation[3]. Systematic observations of latitude variations have been made since the turn of the century and clearly indicate the presence of an oscillation with this 14 month period (see Fig. 1). The amplitude of this oscillation has a maximum of about 0.3 sec of arc, that is the inclination of the instantaneous axis of rotation to the figure axis does not seem ever to exceed about 0.3 sec of arc.

What prevented this free nutation from being completely damped? Many suggestions of mechanisms to excite the Chandler wobble have been put forward during the past seventy-five years, but none has proved satisfactory. The question is still considered by most geophysicists to be largely unanswered. The purpose of this communication is to describe a new, and admittedly speculative, model that we conceived independently. The idea is based on Fig. 1 which, although extending over too short a time interval to be definitive, appears to have an envelope characteristic of "beat" phenomena. We therefore propose that these latitude variations do indeed exhibit beats, attributable to a mechanical interaction between the upper layer with the remainder of the Earth. We at first contemplated a core–mantle separation, but seismological and magnetic field evidence seems to indicate that the core has insufficient rigidity to possess a free nutation frequency nearly equal to the corresponding frequency of the mantle alone. We were thus led to the supposition, which must be regarded as speculative, that the important interaction effectively separating the Earth into two parts occurs in the upper mantle, perhaps somewhere between the depths of about 400 and 1,000 km in a region where the shear velocities of seismic waves change rather sharply. The separate free nutation frequencies of the two parts, modified by the coupling, can be expected to be present in the Chandler motion. The data (Fig. 1) suggest a beat with a half-period between 40 and 50 years, corresponding to a difference in period of the two component frequencies of between 12 and 10 days, respectively. Results of theoretical calculations, although sensitive to the assumed values for the relevant Love numbers and the differences in equatorial and polar moments of inertia of the two parts, indicate that such a beat period is reasonable for our proposed model. (Of course, if the model proves adequate, the observed period provides a further condition on these properties.)

We suppose that this resonant oscillation is excited asynchronously, through a nonlinear interaction, by the differential luni-solar torques exerted on the two layers. Using a suitably parameterized model, we are investigating numerically the possible motions of this complicated, three degrees of freedom, dynamical system. Apart from the well-known expressions for the luni-solar gravitational torques, the model includes a restoring torque (inertial coupling term), which is proportional to the separation of the figure axes of the two layers, and a viscous torque which is a non-linear function of the difference in angular velocity of the coupled parts. In first approximation both layers are considered rigid. The transfer of the required energy between the two layers seems possible on the basis of preliminary calculations. Quantitative results, to be reported in a subsequent communication, will include the relations between the model parameters and the amplitudes and frequencies of the Chandler motion.

How may this model be checked experimentally? The supposition that a beat frequency is present in the Chandler motion can, of course, be tested conclusively by awaiting future measurements. In fact, data have accumulated for 12 years since Fig. 1 was compiled and would be expected to exhibit a decreasing amplitude in the oscillation. Although the nineteenth century observations may not be very reliable, we intend to re-examine the best of these and, after separating the annual term[1], seek evidence bearing on the predicted amplitude modula-

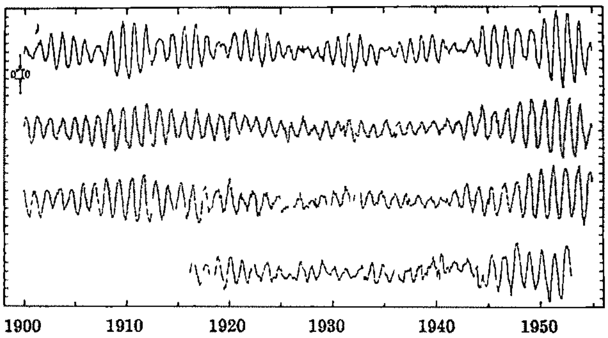

Fig. 1. Variations of the two orthogonal components of the position of the Earth's rotation axis with respect to the axis of the figure (from ref. 1). The top two curves show the unsmoothed observations for one component, before (first curve) and after (second) removal of the seasonal variation. The last two curves, in reversed order, show similar variations for the second component. The first three curves were obtained by the International Latitude Service, the last with the Photographic Zenith Tube at Washington.

tion of the Chandler term The presence of a beat would not definitely establish the correctness of our model, but would provide strong evidence in support of the basic idea Even if the beat were absent, and the apparent change in amplitude illusory, it is still quite conceivable that the excitation of the Chandler motion could take place through the differential luni-solar gravitational torques acting, say, on the core and mantle which may interact through a non-linear coupling

The presence of two important frequency components in the Chandler motion is, of course, also consistent with the apparent breadth of the power spectrum of the polar motion in the vicinity of 0 8 cycles/yr[1] In the past, the corresponding decrease in the amplitude of the auto correlation of the Chandler data—approximately 10 per cent for a 14 month lag—was interpreted as indicating a damping time of approximately a decade and led to suggestions that the free nutation was being excited by random impulses[1] In our model, the amplitude of the auto correlation will also decrease, as observed, but after longer intervals will rise again, the period being equal to that of the beat frequency Furthermore, the problem of the anomalously small Q value for the Earth, inferred from the "damping" of the Chandler motion, is automatically disposed of

If this model of the Chandler wobble proves fruitful, it might be interesting to consider the more complicated case of a non-axially symmetric mantle which may be appropriate for Venus or the Moon

PHYSICS

Dimensional Problem of the Power Law in Rheology

The power law equation, between shear stress, τ, and strain rate, γ, may be written $\dot{\gamma}=k\tau^{\alpha}$ it has often been shown[1,2] to be in accordance with experimental data obtained for many non-Newtonian fluids The equation is open to the logical objection that it is dimensionally inconsistent unless the constant of proportionality, k, is not a true constant at all but has variable dimensions which depend on the properties of the sample under observation Nedonchelle and Schutz[3] have shown experimentally that for one particular non-Newtonian system there is a relationship between the constant of proportionality, k, and the exponent, α, such that the equation may be reduced to a dimensionless form containing three dimensionally stable constants which are independent properties characterizing the material in its environment.

Scott Blair[4] attempted to provide a theoretical basis for the existence of the power law, and in one form[5] of his derivation he introduced four constants, two of which were particular values of a function, which he designated f in his paper In his treatment, this function was subsequently eliminated from the argument, but it can easily be shown that the constants of Nedonchelle and Schutz and of the particular values of Scott Blair for f are closely related

Writing the dimensionless equation of Nedonchelle and Schutz in the form

$$\frac{\dot{\gamma}}{\gamma_0} = \left(\frac{\tau}{\tau_0}\right)^{\alpha} \tag{1}$$

to correspond with the form given here, by replacing their D by γ and their a by $1/\alpha$, gives, on taking logarithms

$$\log \dot{\gamma} - \log \dot{\gamma}_0 = \alpha \log \tau - \alpha \log \tau_0 \tag{2}$$

From the theoretical derivation of Scott Blair, α is the ratio of two constants, which he denotes by a and b Equation (2) may then be rewritten

$$b \log \dot{\gamma} - b \log \dot{\gamma}_0 = a \log \tau - a \log \tau_0$$

or

$$a \log \tau - b \log \gamma = a \log \tau_0 - b \log \dot{\gamma}_0 \tag{3}$$

Scott Blair gives (his equations (2) and (4))

$$a \log \tau = f_1 - f \qquad b \log \dot{\gamma} = f_2 - f$$

so that

$$a \log \tau - b \log \dot{\gamma} = f_1 - f_2 \tag{4}$$

Combining equations (3) and (4) gives

$$\alpha \log \tau_0 - b \log \gamma_0 = f_1 - f_2$$

This becomes an identity if

$$f_1 \equiv a \log \tau_0 \quad f_2 \equiv b \log \dot{\gamma}_0 \tag{5}$$

These expressions (5) give the relation between the experimentally determinable constants τ_0 and $\dot{\gamma}_0$ of Nedonchelle and Schutz, and the constants of integration f_1 and f_2 of Scott Blair

Thus from the results of Nedonchelle and Schutz, it can be deduced that a minimum of three independent characteristic constants are necessary and sufficient for the power law to be dimensionally acceptable, and these three constants are compatible with the theoretical derivation of Scott Blair.

Luminescent Properties of Rocks, Meteorites and Natural Glasses under Proton Bombardment

Suggestions that some transient lunar events[1] are luminescent phenomena, excited by solar protons, have aroused interest in the luminescent properties of putative lunar surface materials We have studied the luminescence produced in various minerals and meteorites by a beam of 146 MeV protons from the Atomic Energy Research Establishment synchrocyclotron Both our proton flux, about 10^8 protons sec^{-1} cm^{-2}, and the ionization density are many orders of magnitude lower than those used by other workers[2-4], thus we avoid their problems of radiation damage and simulate more closely the conditions on the Moon's surface

Our specimens, powdered to a grain size of 10–100μ, were mounted on stainless steel disks using silicone grease, and viewed through one of a set of seven broad-band interference filters by a single EMI 9558 phototube Provision was made for evacuating the sample enclosure, for cooling the samples to liquid nitrogen temperature and for heating them electrically We thus obtained spectra between 3800 Å and 7400 Å at −180° C, +20° C and +100° C We also studied the thermoluminescence produced by irradiation at −180° C followed by heating, at about 12° per minute, to +180° C

Individual samples will be discussed in detail elsewhere, here we note that they may be assigned according to their brightness, spectra and thermoluminescence into one of several distinct groups, corresponding in the case of geological specimens roughly to their petrological type, and in the case of meteorites to their classes according to the Prior–Hey catalogue[5] These groups and their members are listed in Table 1, which also shows their average integrated light output at −180°, +20° and +100° C, their characteristic thermoluminescence (if any), and the ratio of light output at −180° to that at +100° C (the "cold enhancement factor") In Figs 1 and 2 we show representative spectra, at −180° and +100° C, of members of some of these groups The data are normalized to an intensity of $8\ 7 \times 10^{7}$ protons/sec The absolute magnitude of the brightness was found by calculation from the known parameters of the apparatus.

In geological samples, we note that the luminescent intensities are in all cases similar at +20° C and +100° C, but greatly enhanced at −180° C In similar studies, Nash[3] found that the response of a basalt sample was unaffected by a temperature change from +120° C to −80° C, we also find that a reduction to −80° C does not sensibly alter the response of basalts or granites, but that a further reduction to −180° C has a dramatic effect We show in Fig 3*a* the blue response of a granite specimen as a function of temperature and conclude that between −80° and −180° C the relative probability of radiative transitions increases sharply for these common minerals The granites show this low temperature enhancement most strikingly, their brightness at −180° C is of the same order as that of 0 004″ of *NE* 102*A* scintillator The granites also show an intense red thermoluminescence, with peaks near −140° and −30° C, a typical glow curve is shown in Fig 3*b* Energy efficiencies at +20° C varied between about 10^{-5} for the ultrabasic rocks, and about 2×10^{-4} for the granites, assuming an optical depth of 40μ This represents excellent agreement with Nash[3] (energy efficiencies typically 10^{-4}–10^{-5})

Of meteorites, we studied eleven chondrites and three achondrites Our results at +20° C agree well with those of Geake and Walker[2] The enstatite achondrite Khor Temiki was by far the most intensely luminescent Our spectrum for this, together with that of Geake and Walker for comparison, is shown in Fig 2*a* The effects of temperature variation are interesting Some classes of meteorite are brighter at +100° C than at −180° C, unlike any terrestrial rocks we studied This behaviour, typified by a cold enhancement factor less than unity, is accompanied by thermoluminescence near to or above room temperature We show in Fig 3*d* the red thermoluminescence of Khor Temiki, with, for comparison, the glow curve obtained by Sun and Gonzalez[4] for Cumberland Falls, another enstatite achondrite The recent fall at Barwell seems anomalous In all respects, it resembles the bronzites more than the hypersthenes with which it is classified[6] on a mineralogical basis Figs 2*b*, *c* and *d* show the spectra at −180° C and +100° C of Ogi (a typical bronzite), Barwell and Sinai (a hypersthene), respectively This observation seems significant and (in view of the clear mineralogical distinctions[7] between the classes of chondrites, particularly falls) somewhat surprising

Finally, we studied five specimens of tektites and three terrestrial glasses Four of the tektites are very similar, they have featureless spectra of low intensity and exhibit only a small low temperature enhancement and no thermoluminescence The Moldavite, on the other hand, has a strong orange-red peak and a total light output about five times that of the others Fig 2*e* compares its spectrum at +20° C with that of the Australite, and with the low temperature spectrum of Ries impactite glass The latter's resemblance to the Moldavite is intriguing, but the difference in cold enhancement factors argues against any genetic relationship between these two geographically associated glasses

Our observations of the intense thermoluminescence of granites suggest an explanation of the transient red glow

seen repeatedly in regions of the moon which, from their distribution, are believed[8] to be prone to tectonic disturbances In such active regions it may sometimes happen that cold sub-surface material, possibly granitic, is suddenly disturbed and exposed to surface insolation, a previous history of low-temperature irradiation may then give rise to visible thermoluminescence Using values for proton fluxes cited by More and Tiffany[9], we calculate, for example, that lunar material at a depth of about 10 g cm^{-2} will absorb about 10^{10} MeV g^{-1} cm^{-2} y^{-1} Such irradiation at[10] − 70° C for about half a million years might then yield, on sudden heating, light outputs of the same order as that of reflected sunlight

THE SOLID STATE

Annealing of Single Phase Polycrystalline Sulphide Ores

In two earlier communications[1,2] it was demonstrated that the grain boundary shapes in many sulphide ores could be ascribed to interfacial free energy requirements, and thus that their grain structures were analogous to those of metals and ceramics It was also suggested that many ores had been naturally annealed

Subsequent work has confirmed the importance of interfacial free energies in the development of grain shape, but it has also shown that the fully annealed state is far less common than was originally thought In fact it now seems that the fully annealed state is rare among granular ores of "massive" type—a conclusion reached as a result of the development of a new, though very simple, method for expressing degree of annealing

Following the earlier work, we began investigating the effects of temperature on the grain structure of single phase sulphide aggregates, and on dihedral angles in two phase and polyphase aggregates It soon became apparent that heating led to a decrease in the spread of angle values as measured on a random polished section, and that this decrease was in some way related to both time and temperature Unknown to us at the time, Ikeuye and Smith[3] had observed an analogous phenomenon in the

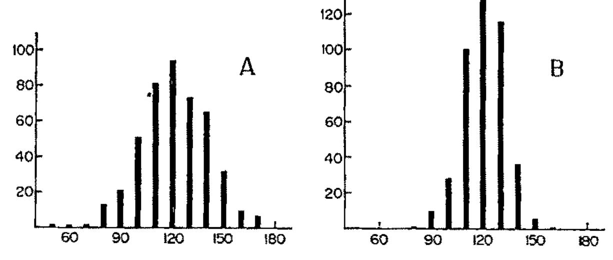

Fig 1 Frequency distribution of angles as measured on a random plane for polycrystalline chalcopyrite ($CuFeS_2$) *A*, Distribution for 450 random measurements before heating, *B*, distribution for 450 random measurements after heating at 300° C for 47 days

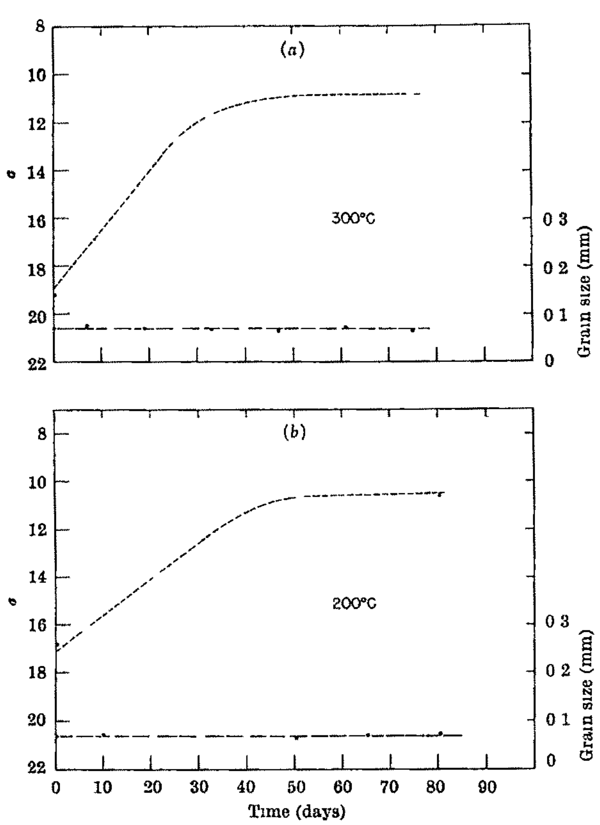

Fig. 2. Plots of changes in spread with time at (a) 300° C, and (b) 200° C for chalcopyrite.

change of the dihedral angle of aluminium–tin alloys (95 per cent to 5 per cent) when cold-rolled and then progressively annealed at 350° and 450° C. By plotting frequency distributions of a standard 400 random angles measured after cold-rolling and then at successive stages of the anneal, Ikeuye and Smith showed a clear change in mode (from 20° to approximately the true dihedral angle of about 60°) and also a decrease in spread of values "as measured". This, of course, involved two phases and thus "impurity diffusion", whereas the present work has been concerned with single-phase grain boundary migration, but the general analogy is clear.

In Fig. 1 are shown frequency distributions of angles, as measured on a random plane, observed by us in polycrystalline chalcopyrite ($CuFeS_2$) from one of the copper orebodies at Mount Isa, Queensland. Fig. 1*A* depicts 450 random measurements on a polished slug of this chalcopyrite prior to heating and Fig. 1*B* depicts a similar 450 measurements on the same slug after heating at 300° C for 47 days. Decrease in spread is clear.

Changes of this kind can be investigated quantitatively by introducing a measure of spread, and then plotting this against time for any chosen temperature. Where a fixed number of angles is measured throughout an experiment, the standard deviation of the frequency of angles as measured is an adequate and convenient index.

In Fig. 2, changes in spread exhibited by two specimens of Mount Isa copper ore heated at 200° and 300° C, respectively, are shown. Apart from occasional deformation twins and the moderate incidence of subgrains, there was no gross microscopical evidence of deformation prior to heat treatment. For each experiment, a single slug (about 2 × 1 × 1 cm) was used. This was etched initially with ammonium hydroxide–hydrogen peroxide and a random 450 angles measured. The etch was then removed, the slug placed in glass tubing which was evacuated and sealed off, and the whole was then heated at the appropriate temperature for the appropriate time. The slug was then removed, repolished, etched and measured again, and so on. It is clear from Fig. 2 that the initial grain boundary arrangement in both cases was immature (that is, not fully annealed). On heating and on the development of atomic mobility, the boundaries began to move towards equilibrium positions, such movement being more or less linearly related to time. On attaining equilibrium (that is, completion of the anneal) the standard deviation, σ, stopped decreasing and the curve flattened as shown. The ultimate spread is rather greater than that which might have been expected from random sectioning itself[4], but this is undoubtedly caused by the slight anisotropy of the chalcopyrite, and by the small impurity content inevitable in any natural ore. Fig. 2 shows that rate of annealing is, as might be expected, related to temperature.

A statistical study of this kind is valuable because it depicts the overall rate of annealing of a polycrystalline aggregate. It is also of interest, however, to observe rates of grain boundary adjustment at individual triple junctions, an experiment first carried out on a metal (a tri-crystal of tin) by Aust and Chalmers[5]. Such an experiment has been carried out by us on a single triple junction in a specimen of galena (PbS) from Coeur d'Alene, Idaho. Unlike the Mount Isa chalcopyrite, this galena showed a high degree of deformation, obvious even to the naked eye. Grains were elongated and often bent, the whole having the appearance of a sulphide schist. The behaviour of the chosen triple junction (that is, the relative movement of the three grain boundaries) at 300° C is shown in Fig. 3. Position 0 indicates the initial positions of the grain boundaries, and positions 1 to 9 show their arrangements as observed at intervals during the 21 days of the experiment. Considering that the temperature was a moderate one from a geological point of view, the amount of movement achieved in this short time is quite remarkable.

We have also obtained results similar to those of Fig. 2 for galena and sphalerite. Rates of annealing for the three minerals are generally comparable and increase fairly systematically with temperature. Current experiments are concerned with the low temperature regions in an attempt to estimate activation temperatures for grain boundary movement in the more common sulphides.

In view of the low temperatures at which grain boundary movement can be induced in sulphides, and the rapidity with which this progresses, it is perhaps surprising

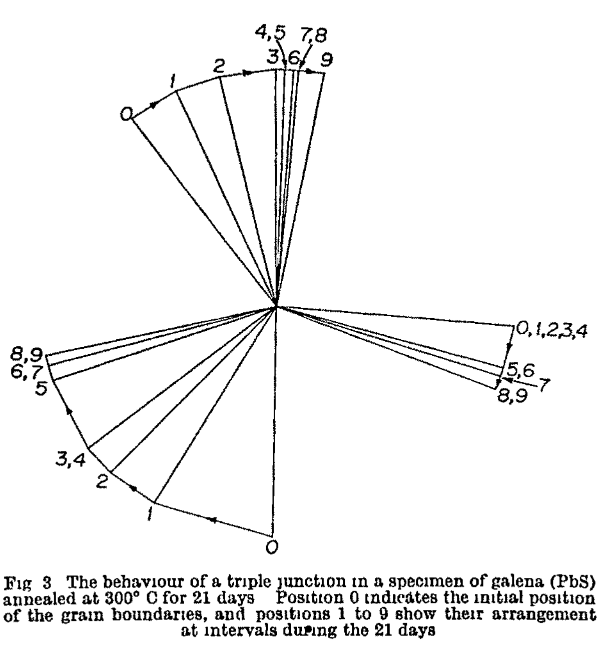

Fig. 3. The behaviour of a triple junction in a specimen of galena (PbS) annealed at 300° C for 21 days. Position 0 indicates the initial position of the grain boundaries, and positions 1 to 9 show their arrangement at intervals during the 21 days.

that any sulphide ores remain unannealed in nature It leads us to suspect that they may be a good deal less static than has been generally thought, and, in fact, that they are being more or less continuously deformed and annealed It follows from this, at least for "massive" ores, that present textures are unlikely to indicate the original physical nature of a deposit or the processes by which it was formed

This work has been carried out under the auspices of the Committee on Experimental Geology and Geophysics at Harvard University, and the Broken Hill Mining Managers Association, and we wish to acknowledge the generous support of both of these We also wish to acknowledge the important part played by N Gow in the initial stages of the investigation, and the helpful advice of Professor Cyril Stanley Smith as it progressed

MOLECULAR STRUCTURE

Interaction between Model Compounds of Actinomycin *D* and DNA: DNA Dependent RNA Synthesis

DIMETHYL-actinocinyl-*bis*-(carboxylate) (AMD 1) and dimethyl-actinocinyl-*bis*-(L-threonate) (AMD 2) bind to the double stranded DNA (see following article) by a mechanism similar to that suggested for aromatic hydrocarbons[1] The binding sites may be related to conformational defects the concentration of which can be drastically reduced by addition of spermidine This is very likely the result of a re-ordering of the Watson and Crick model in solution caused by a stereospecific complex between the polyamine and DNA (refs 2 and 3)

This conclusion strongly suggests that in contrast to actinomycin *D* (ACT *D*), no specific sites are involved in the binding of AMD 1 and AMD 2 to DNA Some correlation has been found to exist for actinomycin between interaction in specific binding sites and inhibition of DNA-dependent RNA synthesis in the presence of RNA polymerase[4], and so we decided to study this reaction in the presence of AMD 1 and AMD 2.

For this purpose, DNA–AMD 1 and DNA–AMD 2 complexes to be used as templates in the RNA synthesis were prepared by equilibration of fine crystals of the two compounds with DNA (Sigma, Type 1) solutions in the cold (4° C) for 4 days and centrifugation, as described in the following article A sample of DNA solution was treated in the same way and used as control RNA polymerase (Miles) from *Micrococcus lysodeikticus* with an enzyme activity of 700 U/mg (ref 5) was used Reactions were performed at 30° C, 10 min in a final volume of 0 3 ml containing 0 1 molar *tris* *p*H 7 5, 2 5 mmolar $MnCl_2$, 1 6 mmolar spermidine hydrochloride (Fluka), 1 mmolar CTP, GTP, UTP and ^{14}C-ATP (2,100 c p m / mμmole), and 200 mμmoles of DNA control or DNA-AMD 1 or DNA-AMD 2 and 4 μg of the enzyme The inhibition of RNA synthesis by actinomycin was studied in the same experimental conditions, by adding to the DNA control increasing amounts of actinomycin *D* (a gift from Merck, Sharp and Dohme Research Laboratories)

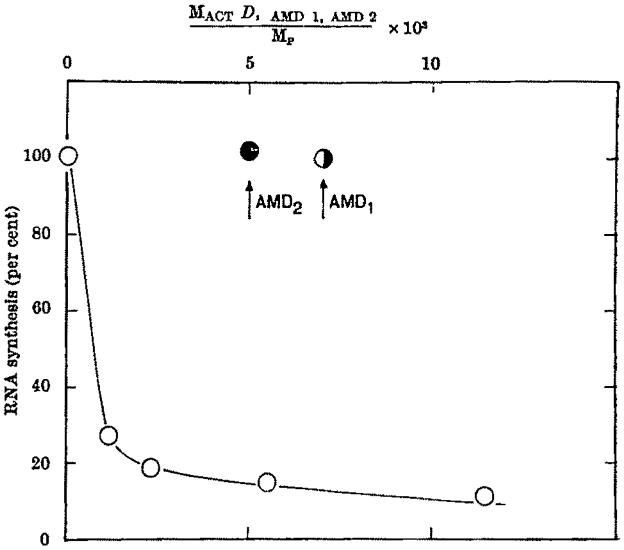

Fig 1. Percentage of RNA synthesis in presence of ○, actinomycin *D*, ◑, AMD 1, and ●, AMD 2 100 per cent corresponds to the incorporation of 2 mμmoles of ^{14}C-AMP For experimental details see text

The reaction was terminated by chilling in ice and adding an equal volume of cold 10 per cent trichloroacetic acid, the precipitate was collected on a 'Millipore' filter and washed extensively with cold 5 per cent trichloroacetic acid. The filters were dried and counted in a liquid scintillation counter (Nuclear Chicago). The results of these experiments are shown in Fig 1 Compounds AMD 1 and AMD 2 do not inhibit the DNA-dependent RNA synthesis and give the same results as the DNA control at concentrations comparable with those of actinomycin *D* which inhibits the reaction more than 80 per cent. In absence of spermidine the extent of the RNA synthesis is 25 per cent lower for both DNA control and DNA-AMD 1 or DNA-AMD 2

These results indicate that specific binding of actinomycin *D* to DNA which causes inhibition of RNA synthesis must necessarily involve the peptide lactone, although the isolated aromatic moiety of actinomycin can also interact with DNA

Interaction between Model Compounds of Actinomycin *D* and DNA: Physicochemical Studies

THE remarkable inhibitory effect of actinomycin *D* on DNA dependent RNA synthesis has been correlated with its ability to interact in a specific way with the DNA template[1]. The nature of the sites of interaction has

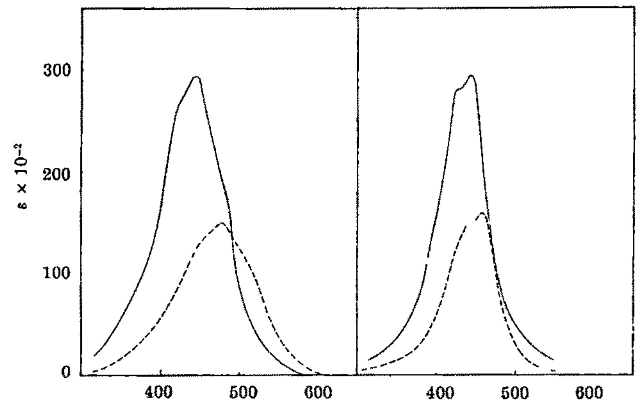

Fig 1 Absorption spectra of AMD 1 (left) and AMD 2 (right) in an aqueous solution of DNA (- - - -) and in water (———)

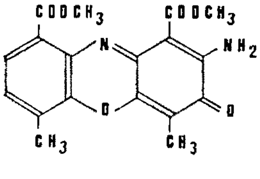
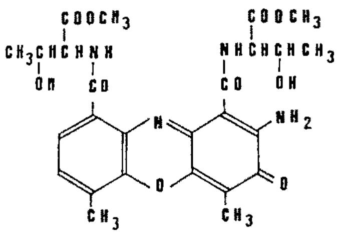
been investigated by physicochemical and biochemical methods[2-4] For this purpose several chemical modifications of the actinomycin have been tried Studies of simple chemical analogues of actinomycin which lack the peptide lactone moiety have, however, probably been discouraged by the great decrease in water solubility which is produced by the removal of the non-phenoxazone region of the molecule Previous experiments in our laboratory have provided useful information on the interaction between DNA and polycyclic aromatic hydrocarbons[5,6], which are sparingly soluble in water, through the introduction of a technique based on solubilization phenomena This method has been used in the present work in order to study the interaction of DNA with two model compounds containing the chromophore group of actinomycin



AMD 1
Dimethyl-actinocinyl-bis-(carboxylate)



AMD 2
Dimethyl-actinocinyl-bis-(L-threonate)

These compounds were prepared from 2-methoxy-toluic acid (Aldrich) through either five or six steps, respectively[7-9] Their solubilities in DNA solutions and in water were determined according to the technique described earlier[5,6] Fine crystals of AMD 1 and AMD 2 were equilibrated with solutions of DNA (Sigma, type 1) or with doubly distilled water for 3 days at 25° C by gentle shaking in the dark

After centrifugation at 60,000*g* for 1 h in the Spinco LHV ultracentrifuge, or filtration through sintered glass G4, the solutions were extracted with chloroform and the concentration in the organic layer was determined from the absorption at 437 mμ for AMD 1 ($\varepsilon = 27{,}000$) and at 444 mμ for AMD 2 ($\varepsilon = 27{,}800$) In Table 1 the solubilities in water and in DNA solutions are reported

Table 1

Compound	Solubilities at 25° C in Water	 DNA solution* (after deduction of the solubilities in water)
AMD 1	$1\ 6 \times 10^{-6}$ moles/l	$3\ 2 \times 10^{-5}$ moles/l
AMD 2	$1\ 0 \times 10^{-6}$ moles/l	$1\ 2 \times 10^{-5}$ moles/l

* DNA concentration 4 m equiv /l phosphate

The solubility in water of both compounds is extremely low compared with that of actinomycin[10] In the presence of DNA, however, there is a marked increase In Fig 1, the absorption spectra of AMD 1 and AMD 2 in water and in DNA solution are shown As in the case of actinomycin[1], a marked red-shift, 31 mμ for AMD 1 and 13 mμ for AMD 2, and a hypochromic effect (AMD 1, $\varepsilon_{475} = 15{,}000$, AMD 2, $\varepsilon_{457} = 16{,}000$) are observed in DNA solution with respect to the aqueous solutions

Both the solubilization of AMD 1 and AMD 2 in water, induced by DNA, and the red-shift of the absorption spectra, are very reminiscent of similar effects which were observed in the case of aromatic hydrocarbons[5] For the latter compounds it has been proposed that their molecules are inserted into defective regions of double stranded DNA and establish perpendicular interactions with the bases The crystal and molecular structures of complexes between aromatic hydrocarbons and a fully methylated purine strongly support this model[11-13]

A similar explanation could apply to the interaction between DNA and AMD 1 and AMD 2 The average number of phosphorous atoms per molecule of AMD 1 and AMD 2 bound can be calculated from the data in the table after making allowance for the solubilities in water The values so obtained are 1 44 and 1 125 which are of the same order of magnitude as those obtained for 3,4-benzpyrene.

As a further control of the hypothesis of a common mechanism for the binding of AMD 1 and AMD 2 and aromatic hydrocarbons to DNA, the influence of spermidine in the solubilization of AMD 1 and AMD 2 in the presence of DNA was studied

The curves of Fig 2 compare very closely with a similar curve showing the effect of spermidine in the binding of 3,4-benzpyrene which was studied with the same technique[6] As in the case of aromatic hydrocarbons the decrease of binding sites for AMD 1 and AMD 2 which was brought about by addition of spermidine can be interpreted as being caused by the elimination of the conformational defects as a result of a stereo-specific complexing of the polyamine to DNA[14] In conclusion, whereas actinomycin presents a strong binding to specific sites followed by a weak extensive binding, according to the mechanism proposed for the insertion of AMD 1 and

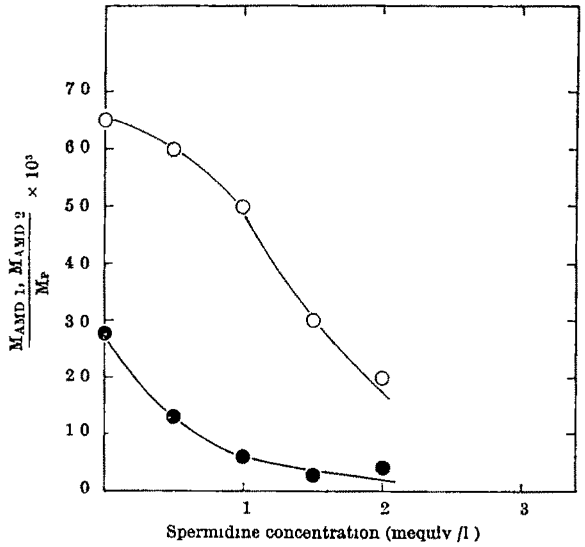


Fig 2 Ratio $\frac{M_{AMD\,1}, M_{AMD\,2}}{M_P}$ corresponding to the number of (○) AMD 1 moles $M_{AMD\,1}$ or (●) AMD 2 moles $M_{AMD\,2}$ solubilized/mole of DNA monomer unit M_P, expressed as phosphorus equivalents, as a function of spermidine concentration DNA concentration 2 mequiv /l phosphate Buffer 10^{-2} molar sodium chloride – 10^{-3} molar sodium citrate, pH 7 1

AMD 2 in conformational defects of DNA, no specificity should be expected in this latter case This is regardless of the similar optical changes which were observed when actinomycin and AMD 1 or AMD 2 interact with DNA

Molecular Structures of Propargyl Alcohol and Propargyl Amine from Microwave Spectra

PROPARGYL alcohol and propargyl amine are of particular structural interest, because they belong to the rare class of substituted derivatives of methanol and methylamine in which the only possibilities of rotational isomerism are those associated with the COH or CNH_2 groups We have assigned microwave spectra for six isotopic forms of propargyl alcohol and for the normal form of propargyl amine The moments of inertia show that the rotamers concerned are those in which the OH and both NH bonds occupy gauche positions, that is, subtend dihedral angles in the region of 60° with respect to the acetylenic group. In the alcohol, the properties of the potential function for internal rotation are reflected in the occurrence of spectra of molecules in a very low-lying excited state and in the occurrence of series of spectral lines with first-order Stark effects

Table 1 ROTATIONAL CONSTANTS

The spectroscopic constants are shown in Table 1 For the alcohol, observed transitions are all caused by the component of the dipole moment in the *A*-axis of inertia, a total of some hundred lines were assigned on a rigid-rotor basis For the amine, lines caused by components of the dipole in both the *A*- and *B*- axes were assigned

The spectrum of the alcohol consists of two chief series of lines, the intensities of one series being only slightly greater than those of the corresponding members of the second For convenience, we have distinguished the constants for the stronger series as those of the ground state (state 1) and those for the other series as belonging to a very low-lying excited state (state 2) A number of lines caused by other states of the molecules are also present With any reasonable set of structure parameters the constants of all forms correspond convincingly only with those expected for the gauche rotamer In particular, the changes in *B* and *C* accompanying deuteration can be accounted for only with this geometry, which is that expected by analogy with the conformation found for allyl alcohol[1] Since beginning this work, we have learnt of similar measurements on propargyl alcohol by Dr E. Hirota[2], at the University of Tokyo, and we are grateful to him for allowing a comparison of the data obtained by our two groups Agreement of the rotational constants is very good, and Dr Hirota has made a considerably deeper study of the internal rotation problem, which we shall accordingly not discuss in detail here The suggestion that the low-lying excited states arise from a rather easy tunnelling of the OH proton from one of the two equivalent gauche positions to the other fits well with Dr Hirota's theoretical analysis of the spectra, including the series of lines with first-order Stark effects

The rotational constants for propargyl amine, all of which can be evaluated with high accuracy, show that four hydrogen atoms are outside the HCCCN plane, and thus the spectra are those of the form in which the NH_2 group straddles the acetylenic bond In accordance with this we have not found lines at the accurately predicted frequencies where absorption caused by any *C*-component of the dipole moment would lie Support is also found in the nuclear quadrupole coupling constants for nitrogen, which have the values

$$eqQ_a = -3\ 00\ \text{MHz},\quad eqQ_b = 1\ 34\ \text{MHz},\quad eqQ_c = 1\ 66\ \text{MHz}$$

The coupling tensor is thus roughly symmetrical about the *A*-axis of inertia and the constants are approximately consistent with the lone-pair electrons on the nitrogen being directed roughly along the *A*-axis This would be expected for the proposed rotamer, but not for the other rotamer in which the lone pair is adjacent to the carbon–carbon triple bond No intense satellite spectra have been observed for the amine, in contrast with the alcohol, and this, too, conforms with the proposed geometry

We are continuing to seek spectra of the alternative rotamers of both these substances, and it is hoped that evidence of the importance, or otherwise, of these will be obtained from high resolution infrared studies of both molecules, over a range of temperatures, which are in progress Work on the microwave spectra is also being extended in order to obtain more detailed structural information

Empirical Correlation between the Molecular Electric Field Gradients and the Average Molecular Polarizabilities of some Halogen Compounds

A NUCLEAR quadrupole resonance signal[1] is split into two components by electrostatic fields[2] with up to maximum field strengths of 50 kV/cm The separation between the two components is a linear function[2] of the polarizability of the molecular species under investigation The aim of this communication is to demonstrate the general validity of this particular relationship[2] which is in fact independent of any restricting experimental conditions, for example application of an electrostatic field (Stark effect[2]) Although there are relatively few compounds for which both the nuclear quadrupole resonance and molecular polarizability data are available, the general validity of the correlation between the molecular polarizability and nuclear quadrupole resonance parameters, such as the molecular electric field gradients q_{zz}, can be demonstrated conclusively in the series of the homologous compounds CH_3Cl, CH_2Cl_2 and $CHCl_3$ The relevant experimental data[3-7] are shown in Table 1 and illustrated in Fig 1

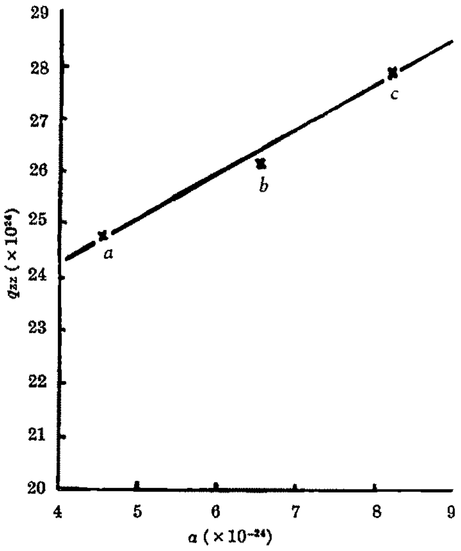

Fig 1 Linear correlation between the molecular electric field gradient q_{zz}, and the average molecular polarizability $\bar{\alpha}$ of the non-spherical molecules CH_3Cl (*a*), Ch_2Cl_2 (*b*) and $CHCl_3$ (*c*)

The molecular electric field gradients, q_{zz}*, used for Fig 1 were calculated from the nuclear quadrupole resonance frequencies of chlorine-35 in the molecules under investigation It should also be mentioned that the electron polarizability[8,9], $P_E + P_A$, is linearly related to the molecular electric field gradient

The existence of the general correlation implies that for the compounds considered a similar relationship might hold for the nuclear quadrupole resonance and Raman data because the appearance of Raman vibrations depends upon the molecular polarizability, which in turn is related to the molecular electric field gradient It is therefore interesting to note that if the Raman active $\nu_{C-Cl}(\pi)$ A_1 frequencies[10] (expressed in wave numbers) are plotted against the nuclear quadrupole resonance frequencies, the points representing the various chloromethanes fall on a smooth curve (see Fig 2)

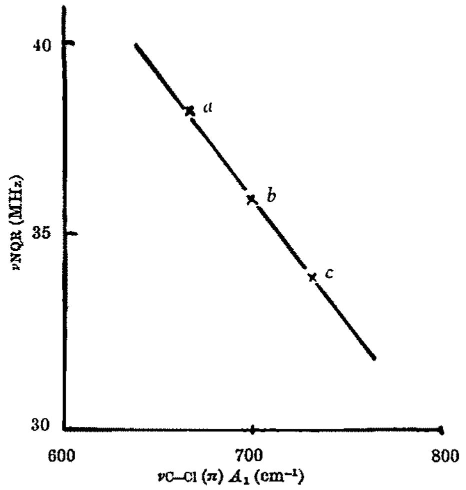

Fig 2 Linear correlation between the nuclear quadrupole resonance (NQR) frequency and the ν_{C-Cl} (π) A_1 Raman vibration of the non-spherical molecules CH_3Cl (*a*), CH_2Cl_2 (*b*) and $CHCl_3$ (*c*)

The Raman frequencies used in Fig 2 are summarized in Table 1

In the series of the chlorine derivatives of methane carbon tetrachloride seems to behave anomalously with respect to the rule developed This suggests that in the case of spherical molecules other rules are necessary to describe the dependence of the molecular electric field gradient on the molecular polarizability The new correlation (equation (3)) can be deduced in the following way

According to Clausius[11] and Mosotti[12], the molecular polarizability of sphere-like molecules is, to a good approximation, a function of the third power of the molecular radius R,

$$\alpha = R^3 \tag{1}$$

On the other hand, the molecular electric field gradient at the chlorine nucleus is a function[13] of the inverse of the third power of the average distance, r, between the quadrupolar nucleus and the $3p_z$ valence electron of chlorine,

$$q_{zz} = (-2)\frac{2l}{2l+3}\left\langle\frac{1}{r^3}\right\rangle_{3p} \tag{2}$$

Combining equation (1) with equation (2) gives

$$q_{zz} \sim (-2)\frac{2l}{2l+3} \times \left(\frac{1}{\alpha}\right) \tag{3}$$

From equation (3) it would be expected that in the case of sphere-like molecules the molecular electric field gradient is proportional to the inverse of the molecular polarizability Equation (3) takes into account the fact that the quotient $1/\alpha$ concerns the sphere-like molecule as a whole while $<1/r^3>_{3p}$ characterizes one of the four chlorine atoms of the tetrachloride

The validity of equation (3) can be checked with the series of compounds CCl_4, $SiCl_4$, $GeCl_4$ and $SnCl_4$ For the graphic representation of equation (3), the electron polarization[8,9] values P_{E+A} of the tetrachlorides are used, for the molecular polarizability is not available in all four cases This procedure is justified because according to the equation

$$P_E + P_A = \frac{n_\infty^2 - 1}{n_\infty^2 + 2} \times \frac{M}{\rho} = \frac{4\pi}{3} \times N \times \alpha$$

the electron polarization is proportional to the molecular polarizability Fig 3 shows a plot of the molecular electric field gradient of sphere-like molecules against the inverse of the electron polarization •

---

* The molecular electric field gradient was calculated with the aid of the following formula[21]

$$\nu = \frac{e^2 Q q_{zz}}{2h}$$

where e is the electronic elementary charge, Q is the electric nuclear quadrupole moment of ^{35}Cl, q_{zz} is the molecular electric field gradient at the ^{35}Cl nucleus h is Planck's constant and ν is the pure nuclear quadrupole resonance frequency

Table 1

Substance	Nuclear quadrupole resonance frequency of ^{35}Cl (at 77° K)	Molecular electric field gradient q_{ZZ}	Average molecular polarizability $\bar{a}$	Electron-polarization (P_E+P_A)	$\nu_{C-Cl}(\pi)$ A_1 Raman frequency (cm^{-1})
CH_3Cl	34 029 MHz (ref 3)	24 75 × 10^{24} cm^{-3}	4 56 × 10^{-24} cm^3 (ref 7)	13 6 cm^3 (ref 8)	732 cm^{-1} (ref 10)
CH_2Cl_2	35 991 MHz (refs 3–5)	26 17 × 10^{24} cm^{-3}	6 48 × 10^{-24} cm^3 (ref 7)	20 cm^3 (ref 8)	700 cm^{-1} (ref 10)
$CHCl_3$	38 254 MHz (refs 3, 4, 6)	27 81 × 10^{24} cm^{-3}	8 23 × 10^{-24} cm^3 (ref 7)	26 6 cm^3 (ref 8)	667 4 cm^{-1} (ref 10)

As indicated by Fig 3, equation (3) describes in a fairly satisfactory manner the linear dependence of the molecular electric field gradient upon the inverse of the electron polarization, and therefore also upon the inverse of the molecular polarizability in all cases except that of $SiCl_4$ The anomalous behaviour of $SiCl_4$ with respect to equation (3) is a consequence of the particular double bond character which causes both the silicon–chlorine bond distance and the chlorine nuclear quadrupole resonance frequency to deviate irregularly from those of the homologous tetrachlorides A further reason is a possible strong deviation of solidified $SiCl_4$ from the spherical symmetry which is characteristic of this molecule in the gaseous state In this regard it should be noted that the nuclear quadrupole resonance spectra of the tetrachlorides of the elements of the fourth chief periodic group can only be recorded in the solid state (that is, at 77° K) The experimental findings relevant to the particular problem of $SiCl_4$ are summarized in refs 14 and 15

Table 2

Substance	Nuclear quadrupole resonance frequency of ^{35}Cl (at 77° K)	Molecular electric field gradient q_{ZZ}	Electron-polarization (P_E+P_A)
CCl_4	40 6 MHz (refs 3, 4, 6) (average value)	29 52 × 10^{24} cm^{-3}	28 2 cm^3 (ref 8)
$SiCl_4$	20 464 MHz (ref 3)	14 88 × 10^{24} cm^{-3}	28 7 cm^3 (ref 9)
$GeCl_4$	25 746 MHz (ref 3)	18 72 × 10^{24} cm^{-3}	38 cm^3 (ref 8)
$SnCl_4$	24 294 MHz (ref 3)	17 66 × 10^{24} cm^{-3}	45 5 cm^3 (ref 8)

Although the data considered are rather limited in number, it is conclusively shown that the molecular symmetry determines the nature of the dependence of the molecular electric field gradient upon the molecular polarizability The results presented thus supplement various empirical correlations put forward For example, Gerdil[16] showed that a linear correlation exists between the nuclear quadrupole resonance and infrared absorption frequencies (thus continuing earlier investigations by Lucken and Whitehead[17]) Further, Iredale[18] related nuclear quadrupole resonance frequencies to polarographic half-wave potentials, and Meal[19] and Bray and Barnes[20] demonstrated a linear correlation between nuclear quadrupole resonance coupling constants of substituted chlorobenzenes and the Hammett σ values of the substituents

BIOCHEMISTRY

DNA Dynamics in Rat Granulopoiesis studied by Cytophotometry

THE theory that the DNA content of cells remains constant has been widely accepted, but some workers[1–3] presume that DNA content decreases either during the mitosis of the precursor cell (hypoploidy[4], haploidy[5]) or during the interphase maturation of the myelocyte stage into the granulocyte stage Another open question is which myeloid cells are capable of DNA synthesis and mitosis ? Most authors express the belief that these are the myeloblasts, promyelocytes and myelocytes[6,7] Recent evidence, however, indicates that some metamyelocytes can synthesize DNA This has been shown in the bone marrow of the guinea-pig after haemorrhage, by labelling with ^{3}H-thymidine and by cytophotometry[8], in irradiated rats as well as normal rats, by autoradiographic methods[9]; and in humans, by cinematomicrography[10]

These data and the fact that we had previously[11] observed division in the more differentiated myeloid cells of rats justified an investigation to find out, by different methods, whether DNA synthesis and mitosis could be seen in rat metamyelocytes in homoeostatic conditions

Myeloid cells were obtained from twenty Wistar rats of either sex weighing 80–120 g The animals were decapitated, the bone marrow plug was removed and

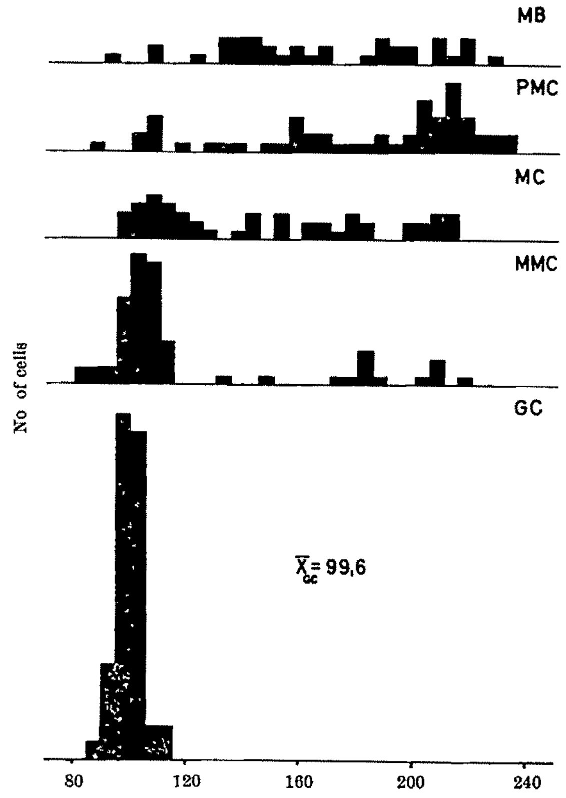

Fig. 1. Histograms showing DNA content in myeloblasts (MB), promyelocytes (PMC), myelocytes (MC), metamyelocytes (MMC), and granulocytes (GC) of myeloid cells.

thoroughly mixed with Tyrode solution by careful shaking. The cells were sedimented on quartz plates, and fixed in a 9 : 1 mixture of methanol and formalin, stained by the Feulgen reaction, and mounted with 'De Pe *X*' medium. DNA content was measured with an Opton *Umsp*-I in monochromatic light of wavelength 560 mμ, and expressed in arbitrary units. Differential diagnoses were made in a phase contrast microscope fitted with an ocular micrometer (×1,250). The stages of maturation were identified by the criteria described earlier[11]. The DNA content in 306 myeloid cells was recorded in five compartments: myeloblasts, promyelocytes, myelocytes, metamyelocytes and granulocytes. Histograms are shown in Fig. 1.

The diploids fell within the range of 85–115 arbitrary units. These were the granulocytes and most of the metamyelocytes. The rest of the metamyelocytes were hyperdiploids and tetraploids. Measurements showed them to amount to 21 per cent, but because we had selected, rather arbitrarily, the more intensely Feulgen-reactive metamyelocytes, it is safe to say that they amounted only to a small percentage. Most, but not all, the metamyelocytes with a higher DNA content were larger than average.

Myelocytes showed the frequency distribution of a highly proliferative population. The slight shift to the right of the peak of the diploid DNA values was probably caused by cells in the early *S* phase.

The DNA content of a large proportion of the promyelocytes fell within the range 190–233 arbitrary units, that is, they were tetraploids. The diploid cells were conspicuous for their small number. The ratio between 2*n*, hyperdiploid, and 4*n* promyelocytes was 1 : 3 : 4, indicating the presence among them of a number of cells with a comparatively long G_2. To establish the most reliable differential diagnoses possible with the phase contrast microscope, only cells with perforated ring shaped nuclei were selected for the DNA measurements, except in the myeloblasts.

The frequency distribution of DNA contents in myeloblasts showed a small heap of diploid cells. They were too few in number to establish the ratio between them and the hyperdiploid and tetraploid cells.

Not one of the 306 myeloid cells measured was of higher than tetraploid values ($AU_{max}=233$, a single promyelocyte).

To test our cytophotometric data, some preparations were stained not with Feulgen but according to the Pappenheim method for autoradiography (unpublished work of G. Rappay and A. Balazs). These studies showed that between 10 and 12 per cent of the metamyelocytes took up ^{3}H-thymidine and that they incorporated approximately as much labelled thymidine as did the promyelocytes with perforated nuclei.

Our findings suggest the following principal conclusions. We found that 50 per cent of the promyelocytes were diploids and hyperploids and that in none of the promyelocytes was the DNA content more than double that in the diploid myelocytes. This seems to contradict the earlier assumption that the division of promyelocytes leads to hypoploid[4] or even haploid[5] amounts of DNA. This assumption is also in marked contrast with evidence produced by Lennartz *et al.*[12] that the time of DNA synthesis (t_S) is twice as long in tetraploid as in diploid cells, whereas in promyelocytes and myelocytes it is about the same length[6,13]. Concerning the earlier assumption that DNA content decreases during interphase maturation[1-3,7,14], we found a shift to the left in the heap of metamyelocytes in relation to the myelocytes. Nevertheless, on cytophotometric evidence alone it is difficult to decide conclusively whether the shift was caused by actual loss of DNA or by the additive effect of cells in the early *S* phase, or to both. The transition between metamyelocyte and granulocyte is easier to interpret adequately. In the present work, the mean DNA value for all metamyelocytes and granulocytes was 121·5 and 99·6, respectively, but if we disregard the hyperdiploid and tetraploid metamyelocytes we find that the difference between the two diploid cell heaps is not statistically significant.

It is now generally accepted[6,7] that the myelocyte compartment is the last in which there is DNA synthesis during granulocytosis. Yet some metamyelocytes, chiefly megametamyelocytes with a nuclear diameter of 13–15μ, had been reported to be hyperdiploids or tetraploids[15]. We made the same observation with metamyelocytes of smaller diameter (10–12·5μ) (ref. 11). We have never encountered greater than tetraploid DNA values (compare reported findings in rabbit metamyelocytes[15]).

The large heap of promyelocytes can be interpreted in either of two ways. (1) These cells are members of a homogeneous population with a long G_2 period. Because t_S has been shown[12] to be independent of $t_{G_1}+t_M$, a shortened G_1 phase looks obvious. No doubt a uniform cell compartment in which the ratio of t_S to t_{G_2} is 1 : 1·3 does strike one as quite unusual. The other, and perhaps more likely, explanation is that there is, at least in the rat, a heterogeneous population of promyelocytes. Because t_S is the same throughout[6,12], while t_G gets longer as myeloid differentiation progresses[6,9,10], it seems justified to postulate, in addition to the incessantly maturing and dividing population, the existence of another promyelocyte population which has a comparatively long G_2. These cells might serve as a rapidly mobilizable reserve in rat bone marrow, as was suggested in some other respects by Gelfant[15] as well as by Lord[9].

We have heard of Morrison's paper (*Trans. Amer. Microsc. Soc.*, 84, 17, 1965) only after completion of our manuscript. His findings are in good agreement with our results and support in some aspects our conclusions.

We thank F. Csemniczky and Mrs E Fazekas-Hollósi for technical assistance

Intermolecular Relationship between Neutral-salt-soluble and Acid-soluble Collagen

Soluble collagen can be extracted from collagenous material with neutral salt solutions and weak acids These extracts display many similar physical and chemical characteristics, but differ significantly with respect to their solubility Neutral-salt-soluble collagen has been shown to be the precursor collagen[1,2], with acid-soluble collagen being the more mature fibre-forming protein[3] The relationship between these soluble collagens which is usually accepted relies on the presence or absence of intramolecular cross links Apart from hydrogen bonds no intramolecular bonds are considered to occur in neutral-salt-soluble collagen On the other hand, acid-soluble collagen is formed as intramolecular bonds are introduced into neutral-salt-soluble collagen Such a relationship alone is insufficient, however, to explain the very different solubility properties of these two forms of collagen It is therefore proposed that neutral-salt-soluble and acid-soluble collagen are related on an intermolecular basis in their native environment, but that their subsequent extraction in mildly acid and basic conditions results in the degradation of terminally located telopeptides, which play a vital part in the properties of these collagen preparations The evidence for this theory is now outlined

A topic which has been the subject of some dispute is the relative proportions of α and β-sub-units in denatured soluble collagens Some workers have shown that neutral-salt-soluble collagen contains only α-sub-units[4,5], while others have shown the presence of β-sub-units as well[2,4,7,8] Some authors[9-11] have reported no differences in the sub-unit composition of neutral-salt-soluble and acid-soluble collagen prepared from the same source A more detailed study of the monomeric nature of neutral-salt-soluble collagen, and its preparation, would seem to explain many of the contradictory findings about the relationship between neutral-salt-soluble and acid-soluble collagen The term monomeric tropocollagen refers here to the native monomer with intact terminally located telopeptide side chains It is postulated[12-14] that side chains rich in acidic residues are present at the one end of the molecule, inducing a small net negative charge, while side chains rich in basic residues are present at the other extremity of the molecule, inducing a small net positive charge A number of workers[15-17] have isolated telopeptides rich in both acidic and aromatic amino-acids, while Cooper and Davidson[18] have reported the presence of three relatively large basic telopeptides While the acidic telopeptides have been shown to be labile in alkaline conditions, the basic telopeptides may be labile in acid conditions The failure to report the presence of such basic telopeptides in many acid-soluble collagen preparations would suggest that they are lost during preparation in weakly acid conditions

In the case of neutral-salt-soluble collagen the initial extract yields a large collagen fraction which when precipitated by lowering the *p*H with acetic acid becomes largely insoluble in 10 per cent NaCl even after very exhaustive extraction The initial ability of such neutral-salt soluble collagen to form insoluble polymeric material as well as to gel at body heat[19,20] would strongly suggest an intermolecular polymerization mechanism involving telopeptide linkages Furthermore, the extraction of the initial collagen precipitate with dilute acetic acid results in a soluble collagen fraction incapable of undergoing vigorous polymerization or gelating at body heat The progressive depolymerization of the initial collagen precipitate in weakly acid conditions resulting in the loss of telopeptide side chains would explain such findings

If native neutral-salt-soluble collagen is the tropocollagen monomer, then the possible dimeric character of acid-soluble collagen must be considered Acid-soluble collagen prepared by repeated phosphate precipitation in alkaline conditions has been fractionated on CM-cellulose yielding the α_3, α_1, β_{11}, β_{12} and α_2 sub-units[21,22] It must be noted, however, that acid-soluble collagen prepared using no phosphate precipitation has been shown to yield major unknown components[23-27] Davidson and Cooper[26] have related four such components to the $\alpha_1\alpha_1$, $\alpha_2\alpha_2$, $\beta_{11}\beta_{11}$ and $\beta_{12}\beta_{12}$ dimeric sub-units, respectively, and attribute their presence to the dimeric nature of the parent material Such a dimeric parent material would explain the β_{22}-sub-unit reported by Bornstein *et al* [28], as well as the presence of only β-sub-units in an acid-soluble extract reported by Bakerman and Hersh[29]

The presence of dimeric sub-units in solutions of denatured collagens immediately stresses the need for extreme caution in the interpretation of sedimentation data Davidson and Cooper[26] have shown that the major $\alpha_1\alpha_1$ and $\alpha_2\alpha_2$ components sediment with the β-sub-units, and suggest that the minor $\beta_{11}\beta_{11}$ and $\beta_{12}\beta_{12}$ components (molecular weights approximately 350,000) may be incorrectly characterized as gamma components A molecular weight of 260,000 for the collagen monomer[30], as well as the wide range of molecular weights and $\alpha \cdot \beta$ ratios reported in the literature, would support such findings Such evidence immediately casts doubt as to the labile nature of the β-sub-unit in certain prescribed conditions when using evidence from sedimentation[10,17,31-33] Mazurov and Orekhovitch[2] found no degradation of the β-sub-unit at *p*H 9 The depolymerization of the $\alpha_1\alpha_1$ and $\alpha_2\alpha_2$ components may in some cases explain such findings

While numerous values for the intrinsic viscosity of collagen appear in the literature (see summary by Kahn and Witnauer[34]), the absence of values extrapolated to zero rates of shear makes any comparison difficult Davison and Drake[30] quote a value of 10 dl /g for pronase treated monomeric tropocollagen at zero rate of shear, and attribute their higher values for untreated acid-soluble collagen (17–20 dl /g) as resulting from the presence of linear polymers Kahn and Witnauer[34] quote a value of 27 dl /g for acid-soluble collagen at low rates of shear, which would support the theoretical supposition that the collagen dimer is terminally linked with a 10 per cent overlap[35], and would display an intrinsic viscosity of approximately 30 dl /g This evidence would also suggest that acid-soluble collagen is dimeric

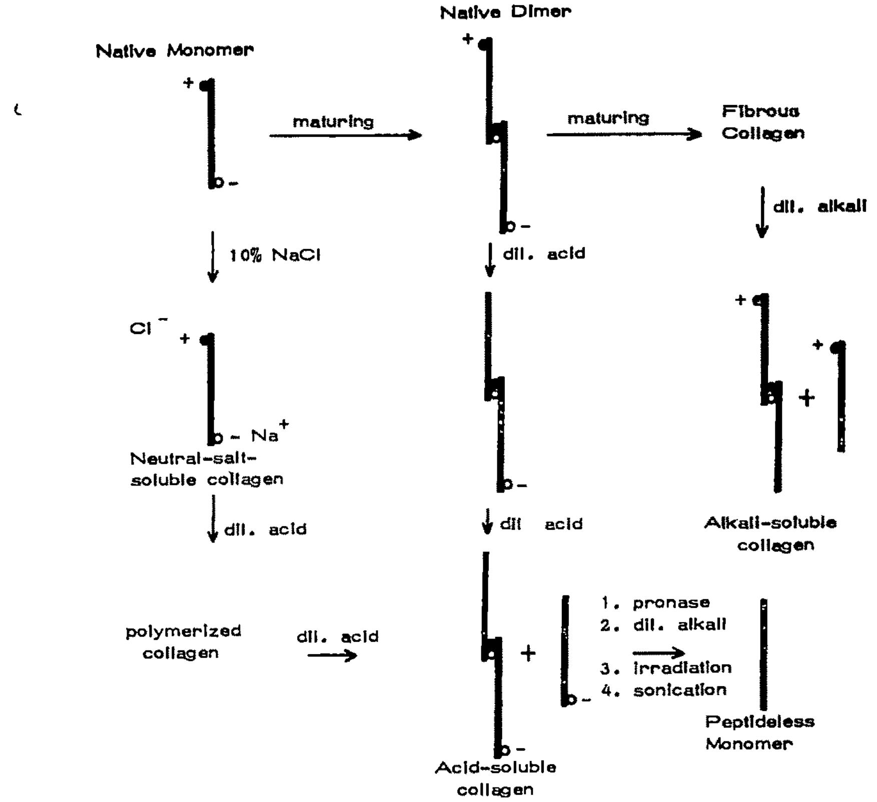

Fig 1 Intermolecular relationships between soluble collagens

When related to the current methods of extracting soluble collagens, much can be explained using this hypothesis First, the preparation of neutral-salt-soluble collagen would initially yield an active monomer which when acidified would yield an insoluble polymer (Fig 1) Subsequent extraction with dilute acetic acid would yield a mixture of soluble inactive monomer and inactive dimer, which on further purification would result in the progressive enrichment of inactive monomeric collagen Second, the preparation of acid-soluble collagen after previous removal of neutral-salt-soluble collagen would result in an initial extract of inactive dimeric collagen which on further purification would be progressively enriched with inactive monomeric collagen In both cases the resultant monomer-dimer content will depend on the number of purification stages carried out, as well as on the *p*H conditions used These conclusions would indicate that native monomeric tropocollagen can only be prepared in a neutral medium of high ionic strength Such a medium would effectively smother any electrostatic interaction of the high active collagen monomer, and so inhibit polymerization (Fig 1)

The term linear polymerization seems to explain the well ordered mechanism of fibre formation from native tropocollagen monomers, while the term aggregation can be applied to those preparations in which the partial or complete destruction of telopeptide side chains has taken place, resulting in an impaired ability of such preparations to form insoluble native fibres

Proposed Procedure for the Allocation of Trivial Names to the Gibberellins

THE symbols A_1, A_2, A_3 and A_4 were originally used by Takahashi *et al.*[1,2] to denote the first four gibberellins, isolated from the fungus *Gibberella fujikuroi* This convenient trivial nomenclature was continued by MacMillan *et al* [3-5], Cross *et al* [6-8], Hanson[9,10] and Galt[11,12] to include gibberellins A_5 to A_{17} Continuity of the sequence gibberellins A_1 to A_{17} has been maintained, and confusion avoided, for the following two reasons First, gibberellins A_1 to A_4 were named by one group at the University of Tokyo and gibberellins A_5 to A_{17} by a second group, who kept in personal contact when the Akers Research Laboratories, ICI, Ltd, where they worked was closed down. Fortuitously, there was no overlap in time between the numbering of these two groups of gibberellins by these two groups of workers Second, Tamura and his group and Mitsui and his colleagues have avoided possible confusion while waiting for an agreed procedure for the allocation of gibberellin A numbers, by using provisional names for their recently discovered plant gibberellins based on their source, namely, Bamboo[13,14], Pharbitis[15], Canavalia-I and -II[16,17], Lupinus-I[18] and Lupinus-II (personal communication from K Koshimizu and T Mitsui) gibberellins

Several plant physiologists have suggested to us that the present circumstances provide an' opportunity to devise an entirely new system of trivial names, based on structural type We believe that this would result in complete confusion Names based on the original source of isolation have obvious disadvantages, for example, Bamboo gibberellin has been found[19] in seed of *Phaseolus multiflorus* We therefore propose that the gibberellin A_1 A_n system of trivial names be extended to include the Bamboo, Pharbitis, Canavalia and Lupinus gibberellins (see Fig 1) We further propose the adoption of the following procedure for the allocation of gibberellin A numbers to future gibberellins One of us (J MacMillan) will allocate consecutive numbers gibberellin A_{24} A_n on request His task will simply be one of book-keeping and the release of a number will imply no judgement on the correct application of gibberellin nomenclature; the naming of a compound by this gibberellin number would

Provisional name	Structure*	Proposed A number	Provisional name	Structure*	Proposed A number
	 HO O CH$_2$ H CO HO CO$_2$H H H CH$_3$	A_{16}†	Pharbitis		A_{20}
	 OH CH$_2$ CO$_2$H H CO$_2$H H H CH$_3$ CO$_2$H	A_{17}	Canavalia-I	 OH CH$_2$ O H CO CO$_2$H H H CO$_2$H	A_{21}
Lupinus-I	 OH CH$_2$ CH$_3$ H HO CO$_2$H H H CH$_3$ CO$_2$H	A_{18}	Canavalia-II	 OH CH$_2$ O H CO CO$_2$H H H CO$_2$H	A_{22}
Bamboo	 OH CH$_2$ CHO H CO$_2$H H H CH$_3$ CO$_2$H	A_{19}	Lupinus-II	 OH CH$_2$ CHO H HO CO$_2$H H H CH$_3$ CO$_2$H	A_{23}

Fig 1 * The depicted absolute stereochemistry is mainly by analogy, except for A_{20} † Isolated as the methyl ester only remain the sole responsibility of the investigator(s). Following precedent, these *A* numbers should be used only for naturally occurring, fully characterized compounds which possess the gibbane skeleton and the appropriate biological properties; *A* numbers need not be used for naturally occurring derivatives of previously described gibberellins, for example, 2-O-acetyl gibberellin A_3 (ref. 20). To help determine whether a suspected new gibberellin is distinct from those previously described, as complete a collection as possible of infrared and mass spectra of the known gibberellins will be held by us both.

These proposals have been discussed with, and approved by, other workers in the field. We hope that they will be generally adopted.

It should be noted that the gibberellin *A* numbers do not necessarily follow the order of discovery. For example, gibberellin A_3 was the first characterized gibberellin and, indeed, the name gibberellic acid takes precedence over gibberellin A_3 although the latter name is now more convenient. Also, gibberellin A_{17} was isolated after gibberellins A_{18} to A_{22}.

A complete list of the gibberellins known at present and their structures is provided by our Fig. 1 and Fig. 1 of Cavell *et al.*[21].

PATHOLOGY

Segmental Demyelination of Peripheral Nerves in Krabbe's Disease

The current literature contains many references to peripheral neuropathies in a variety of conditions[1-4]. This communication describes a peripheral neuropathy associated with Krabbe's globoid cell leucodystrophy which is a progressive heredofamilial neurological disorder of infancy, and is usually diagnosed by either brain biopsy or at necropsy by the demonstration of characteristic "globoid" cells in the white matter. Bachhawat *et al.*[5] have described a deficiency of cerebroside sulphotransferase in the brain of two cases. Clinical descriptions and details of investigations of a series of patients suffering from this rare condition are in preparation.

Peripheral nerves were obtained at biopsy or necropsy in four cases of Krabbe's leucodystrophy aged between 7 months and 21 months. Portions were "snap" frozen or fixed in buffered formalin. Part of one biopsy was processed for electron microscopy. Paraffin sections were stained with haematoxylin and eosin, periodic acid–Schiff (PAS), haematoxylin and van Gieson and Luxol fast blue. Acid phosphatase was demonstrated in cryostat sections of unfixed nerve[6]. Cryostat sections were also stained with toluidine blue, cresyl fast violet, Sudan black, PAS and Luxol fast blue. Nerves from control cases were processed similarly. Nerves fixed in formalin were partially teased and stained with Sudan black in propylene glycol before final teasing from 30 per cent glycerol.

In the paraffin sections, the nerves showed considerably less myelin than the controls, and there was evidence of myelin breakdown. Cryostat sections showed excessive acid phosphatase activity in the Schwann cell cytoplasm (Fig. 1), but no metachromasia could be demonstrated. The acid phosphatase activity was present in fine granular form and at the periphery of vacuoles. Teased nerves showed segmental demyelination (Fig. 2). Some remyelination was also evident.

Electron microscopy provided evidence of an active process in the nerve. Many fibres had large vacuoles containing myelin debris within the Schwann cell cyto-

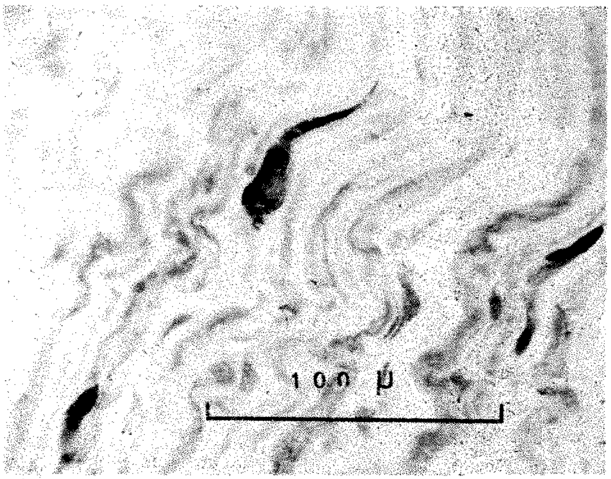

Fig. 1. Sural nerve cryostat section. Acid phosphatase activity in the cytoplasm of Schwann cells.

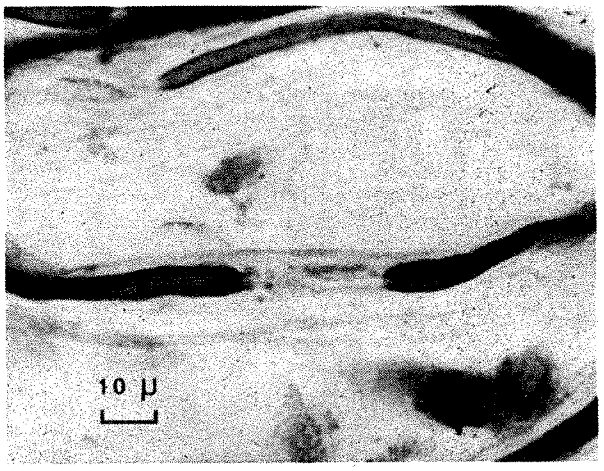

Fig. 2. Teased nerve stained with Sudan black showing a demyelinated segment.

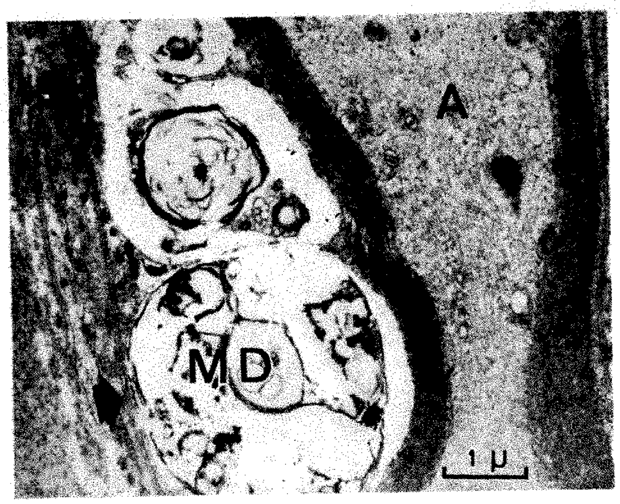

Fig. 3. Sural nerve. Large vacuoles containing myelin debris (*MD*) adjacent to myelin sheath. Axon (*A*) appears normal. Arrows indicate boundary of Schwann cell.

plasm (Fig. 3). Other fibres appeared to be remyelinating and occasional fibres showed the changes of Wallerian degeneration.

The pathological changes associated with Krabbe's globoid cell leucodystrophy have hitherto been thought to be confined to the brain, and previous workers have found no abnormalities in peripheral nerves[7,8]. Allen and de Veyra[9], however, have recently shown in one case "minimal peripheral nerve abnormalities" which they considered to be a late expression of a maximally developed disease. The results obtained in each of our cases show that the nerves of patients with Krabbe's disease are poorly myelinated and that there is segmental demyelination. A deficiency of cerebroside sulphotransferase in Krabbe's disease could explain the findings in the peripheral nerves. The lack of this enzyme would prevent the formation of cerebroside sulphate (sulphatide), an essential component of myelin, and thus the myelin formed would be unstable. It is suggested that in suspected cases of Krabbe's leucodystrophy nerve biopsy may be helpful in establishing the diagnosis, particularly if this is done in conjunction with studies of nerve conduction time, which in each of our cases was found to be markedly retarded.

Metachromatic leucodystrophy from which this disorder must be distinguished can be recognized by deposits of sulphatide staining metachromatically with cresyl fast violet in peripheral nerve and by the demonstration of metachromatically staining cells in the urine[10]. Urinary aryl sulphatase activity is also reduced in this condition[11].

I thank Dr H. G. Dunn, Dr J. Wilson and Professor J. B. Cavanagh for helpful discussion and Dr A. E. Claireaux for access to material.

IMMUNOLOGY

Ability of Leucocytes to recognize some Foreign Gamma Globulins during Pinocytosis

We have previously demonstrated that pinocytosis of autologous immunoglobulins (Igs) altered by physical (heating at 80° C, X, γ or β-rays) or chemical agents ($(NO_3)_2Hg$; $(NO_3)_2Pb$) is significantly increased as compared with unaltered Igs[1,2]. We have now extended our investigations by studying the pinocytosis of unaltered Igs from various species. It is already known that Igs markedly increase pinocytosis by various types of cells[4-8].

Pinocytosis of Igs was investigated by fluorescence microscopy of a mixture of 10^6 guinea-pig peritoneal exudate cells and 6·6 mg of Igs/ml., incubated for 30 min at 37° C. The guinea-pig peritoneal exudate was obtained after two intraperitoneal injections of polyvinylpyrrolidone and contained about 90 per cent of polymorphonuclear leucocytes. Autologous, homologous, human, chicken, tortoise and carp Igs were prepared by chromatography on DEAE 'Sephadex' and labelled with fluorescein isothiocyanate[9]. The pinocytosis index was expressed as the percentage of leucocytes showing fluorescent pinocytic vacuoles[10] (Table 1).

Table 1. INDEX OF PINOCYTOSIS OF VARIOUS GAMMA GLOBULINS BY GUINEA-PIG PERITONEAL EXUDATE LEUCOCYTES

Gamma globulin species	No. of experiments performed	$\bar{x}_e \pm \sigma$	$\bar{x}_p$ *
Autologous	24	15·5 ± 1·1	$14{\cdot}66 < \bar{x}_p < 16{\cdot}34$
Homologous	24	31·9 ± 3·1	$30{\cdot}22 < \bar{x}_p < 35{\cdot}58$
Human Igs	30	45·4 ± 2·7	$44{\cdot}03 < \bar{x}_p < 46{\cdot}77$
Chicken	7	40·51 ± 4·95	—
Tortoise	5	44·42 ± 8·2	—
Carp	7	55 ± 6·03	—

The significance of the results was estimated by the χ^2 test and Student's *t* test. The index of pinocytosis differed for each kind of Igs (autologous, human, reptile, fowl), although differences were not significant from one species to another ($P > 0{\cdot}05$). Fish Igs show a maximum index, significantly different from the autologous and homologous ($P < 0{\cdot}01$), but only doubtfully significant against tortoise Igs ($0{\cdot}01 < P < 0{\cdot}05$).

* The mean population was calculated using the Student parameter (*t*), for a probability of 0·005.

As shown in Table 1, the pinocytosis index for autologous Igs was significantly less than that observed for homologous Igs ($P < 0{\cdot}01$) and this latter was significantly less than the index observed for heterologous Igs ($P < 0{\cdot}01$).

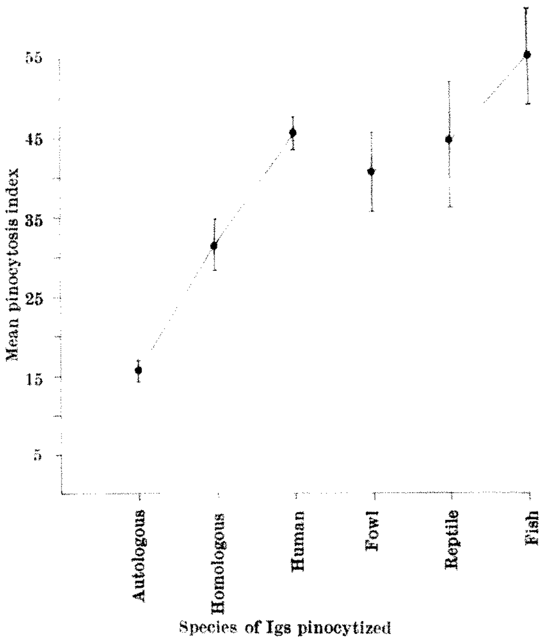

Fig. 1

Our experiments show that polymorphonuclear leucocytes can discriminate between autologous and foreign or autologous immunoglobulins denatured in various ways[1,2].

The mechanism by which discrimination occurs is unknown. Many authors considered that discrimination of foreign or altered matter at the leucocytic level is mediated by opsonins or natural antibodies[11-17]. It seems very likely that the immunological mechanisms of recognition implied in the immune response were evolved from the cruder recognition process which also seems to be involved in our experiments.

As shown in Fig. 1, the pinocytosis index for the heterologous Igs is not obviously related to the phylogenetic distance.

The absence of correlation between the kind of radiations (X, γ, β) and the levels of the pinocytosis index (of irradiated autologous Igs) reported previously[2] also implies a more limited ability of polymorphonuclears to discriminate subtle differences.

We thank Mrs Giorgina Dimitrescu for technical assistance.

Location of Gamma Globulin in the Endocardium in Rheumatic Heart Disease by the Ferritin-labelled Antibody Technique

Gamma globulin can be demonstrated by the fluorescent antibody technique in some biopsy specimens of the left atrial appendage from patients with rheumatic heart disease and also *post mortem* in the heart in cases of acute rheumatic fever[1-5]. The distribution is focal and usually bears no direct relation to cellular rheumatic lesions, although gamma globulin can occasionally be demonstrated in the latter. We have used antibody labelled with ferritin to study the location of gamma globulin in relation to individual components of the endocardium and subendocardium.

Cryostat sections of fresh specimens of left atrial appendage from cases of mitral valvotomy were stained for gamma globulin by the fluorescein-labelled antibody technique (rabbit anti-human gamma globulin antiserum followed by goat anti-rabbit gamma globulin antiserum labelled with fluorescein).

For electron microscopy goat anti-rabbit and rabbit anti-human gamma globulin antisera were labelled with ferritin by the method of Singer[6], with various modifications. These preparations were kindly provided by Professor P. H. Gell. Cryostat sections (60μ thick) of four specimens positive for gamma globulin and four negative specimens were treated with antibody labelled with ferritin either by the double layering or the direct technique similar to the fluorescein-labelled antibody method. After washing for at least 30 min, sections were fixed in Caulfield's buffered osmium tetroxide, and the endocardium was embedded in 'Araldite' and methacrylate. Some sections were treated with phosphotungstic acid during dehydration.

As further controls, one specimen from a case of calcific aortic stenosis negative for gamma globulin by the fluorescein technique was similarly treated, and sections from all specimens were treated with ferritin solution diluted to a colour resembling that of the labelled antisera.

With fluorescent microscopy irregular areas of the endocardium and subendocardium showed specific fluorescence. Only one specimen contained small numbers of cellular lesions in the subendocardium and in some of these there was focal fluorescence. In most areas, however, the gamma globulin bore no relation to cellular lesions and was present in specimens without such lesions.

The tissue had suffered considerable distortion by freezing and autolysis, but most structures were readily identifiable on the electron microscope.

In the control sections, stained with diluted ferritin solution, a small amount of ferritin was seen chiefly in relation to collagen and sometimes in the cement substance between collagen fibrils. A few groups of particles were present in the interstitial spaces, and occasionally were found attached to fibroblasts, macrophages and smooth muscle cells. A similar appearance was noted in the negative specimens treated with labelled antisera and in the control specimens of the positive cases.

In contrast to this, sections containing gamma globulin showed large amounts of ferritin in the endocardium and subendocardium, but in some zones it was almost entirely absent. The ferritin was heavily concentrated in relation to collagen fibrils and when these occurred separately particles were closely applied to the fibrils. With large collagen fibres ferritin was located on and between fibrils and in cross-section could be seen in the cement substance, either closely applied to the fibril or separated from it by a narrow zone. Sometimes small groups of ferritin were seen in the interstitial spaces between collagen fibres. In some of the fibrils with ferritin attached no periodicity could be recognized. Small areas of granular amorphous material were heavily studded with ferritin particles.

The elastic tissue showed only occasional ferritin particles on the surface and the cells of the endocardium showed no more ferritin than in the controls. Only one specimen contained cellular lesions and we failed to locate any in the embedded sections.

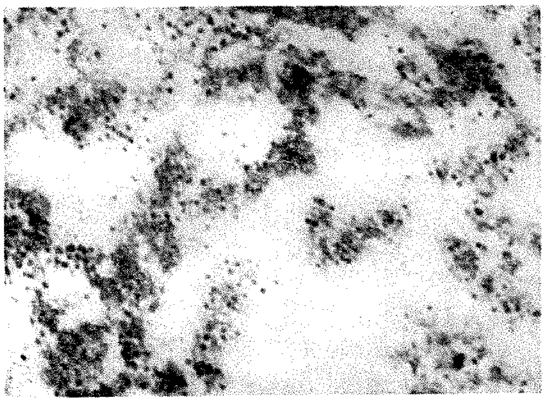

Fig. 1. Collagen fibrils and granular material with ferritin attached. (× 180,000.)

The specificity of the ferritin labelling technique is not very high because of the tendency of ferritin to stick to tissues, and attempts to improve it—for example, by removal of free ferritin—have been disappointing. In our material, the ferritin-labelled antibody was obviously not entirely specific, but the difference between the controls and the positive specimens was so marked that certain tentative conclusions are possible. The chief difference was quantitative and the effect could be recognized with the naked eye after staining by the faint yellowish colour of the sections positive for gamma globulin. The heaviest concentrations of ferritin were in relation to collagen fibrils, some of which showed loss of periodicity, granular material and the cement substance of collagen fibres. We have previously described granular material and fibrils without periodicity within and around cellular rheumatic lesions[7,8]. The possibility that ferritin was in the same situation as acid mucopolysaccharide was considered, but this was not thought to be the case because the distribution of acid mucopolysaccharide, as demonstrated by the colloidal iron method, is principally around fibres and very little is seen within a fibre between the fibrils. In addition, when the dialysed iron method was applied after staining with labelled antibody the distribution of both could be seen on the electron microscope, and although the two sometimes occurred in the same area, the heavy concentration of colloidal iron on the surfaces of fibres contrasted with the heavy concentration of ferritin in relation to collagen fibrils.

In spite of the difficulties of sampling and of non-specific "staining" we believe the differences are great enough between the controls and the test specimens to allow us to conclude that gamma globulin in rheumatic tissue is closely related to collagen fibrils or to the cement substance rather than to the ground substance between fibres.

In previous studies[7,9] we have shown that collagen itself and probably the cement substance take part in the formation of "fibrinoid" in rheumatic lesions. In this connexion the observation of Goldstein *et al.*[10] that a glycoprotein in heart valves cross reacts with streptococcus *A* polysaccharide may be important.

Gamma G4-Globulin Antibody causing Inhibition of Clotting Factor VIII

HAEMOPHILIA results from the absence of clotting factor VIII. The presence of a circulating inhibitor to factor VIII causes a disease which resembles haemophilia. Five patients with inhibitors shown to be γG-antibodies have been reported[1-3].

γG-antibodies can be separated into four subclasses (γG1, γG2, γG3 and γG4) and two types (κ and λ) based on antigenic differences in the heavy and light polypeptide chains, respectively[4]. In this report, the antibody to factor VIII found in one patient is of the γG4 sub-class with κ-type light chains. This is the first demonstration of antibody activity in the γG4 sub-class and the first determination of heavy chain sub-class characteristics of factor VIII inhibitors.

Previous studies of patient G. K.[2] had shown that decreased factor VIII activity was the only clotting deficiency and was caused by a γG-antibody which inhibits factor VIII. In this study identification of heavy chain subclass and light chain type was accomplished by immunoglobulin depletion. Antisera were directed against κ or λ light chains and either γG1, γG2 and γG3, referred to as anti-γG123, or γG4. Anti-γG123 was prepared by injecting Rhesus monkeys with pooled normal γG in complete Freund's adjuvant. The antiserum was absorbed with isolated γG4-myeloma protein and light polypeptide chains from pooled normal human γG. Immunoelectrophoretic and Ouchterlony tests showed that it precipitated only γG1, γG2 and γG3 sub-classes. Anti-γG4 was prepared by immunizing Rhesus monkeys with γG4-myeloma protein. The antiserum was absorbed with light chains, γG2-myeloma protein and hypogammaglobulinemic serum. The resulting antiserum precipitated only γG4-globulins.

Antisera to κ and λ-chains were prepared by immunizing rabbits with κ or λ-Bence Jones proteins in complete Freund's adjuvant. The antisera were absorbed to render them specific for either κ or λ-chains. Difficulties encountered in the clotting assay when whole rabbit antiserum was used were circumvented by precipitating the antiserum with 40 per cent saturated $(NH_4)_2SO_4$ and fractionating precipitates on DEAE-cellulose. Fractions showing antibody activity were used. All antisera were centrifuged to remove lipid and adsorbed with $BaSO_4$ to minimize any direct effect on the clotting time.

Immunoglobulin depletion studies were carried out with inhibitor-rich fractions eluted from a starch block electrophoresis of serum G. K. Aliquots of antiserum were added to the inhibitor fraction, incubated for 1 h at 37° C, 16 h at 4° C, and centrifuged to remove precipitates. Antiserum was added until there was no further precipitation. Preer and Ouchterlony methods confirmed the completeness of absorption.

The inhibitor was assayed by mixing the test sample with normal plasma diluted 1 : 7·5, incubating for 30 min at 37° C, and performing a one stage factor VIII assay[2,5]. Prolongation of clotting time beyond the normal plasma control indicated loss of factor VIII activity caused by the inhibitor. Normal plasma gave an average clotting time of 78 sec (Table 1). When the inhibitor fraction of serum G. K. was added to normal plasma, the time increased to 112 sec. The inhibitor fraction was depleted of either γG1, γG2, and γG3 or γG4 and re-evaluated for inhibitory activity. Complete loss of inhibitory activity followed depletion of γG4-globulins (Table 1). The clotting time of normal plasma plus inhibitor fraction depleted of γG1, γG2 and γG3 remained at 112 sec, indicating no loss of inhibitory activity (Table 1). The clotting time of normal plasma was unaffected by anti-γG4 serum but it was shortened with anti-γG123. This

Table 1. EFFECTS OF IMMUNOGLOBULIN ABSORPTION ON INHIBITORY ACTIVITY

	One stage factor VIII assay: clotting time (sec)		No. of determinations
	Average	Range	
Normal plasma	78	77–80	8
Normal plasma + inhibitor fraction	112	108–115	8
Normal plasma + inhibitor fraction absorbed with anti-γG123	112	110–114	6
Normal plasma + inhibitor fraction absorbed with anti-γG4	80	79–82	12
Normal plasma + anti-γG123	68	68–69	2
Normal plasma + anti-γG4	77	76–78	2
Haemophilic plasma	115	—	1
Haemophilic plasma + anti-γG123	115	—	1
Haemophilic plasma + anti-γG4	116	—	1

Normal or haemophilic plasma was incubated with the test sample for 30 min at 37° C. A one stage factor VIII assay was performed. In solutions containing normal plasma plus test sample, clotting times longer than that for normal plasma alone indicate the presence of a factor VIII inhibitor in the test sample. In solutions containing haemophilic plasma plus test sample, clotting times shorter than haemophilic plasma alone indicate the presence of factor VIII in the test sample.

effect was not caused by factor VIII in the antiserum, for it did not decrease the clotting time of haemophilic (factor VIII deficient) plasma (Table 1). The shortening of clotting time caused by anti-γG123 is unexplained.

To evaluate further the possibility that the inhibition of factor VIII is caused by a non-specific effect of elevated γG4-globulins, an inhibitor assay was performed on serum from another patient containing more than 30 mg/ml. of γG4-myeloma globulin. No factor VIII inhibition was found. Other evidence that inhibition was the result of a true antigen–antibody reaction was obtained from a previous experiment[2] which showed that pepsin digestion, known to destroy the Fc piece of γG-globulins and leave intact the antibody combining site, failed to reduce inhibitory activity.

Similar depletion experiments were carried out using rabbit antisera to κ and λ determinants. Anti-κ serum removed some of the anti-factor VIII activity, while anti-λ had no effect (Table 2). It was impossible to remove all anti-factor VIII activity with anti-κ antiserum. This was probably not caused by λ-type anti-factor VIII, for absorption with anti-λ did not remove any activity. Anti-κ serum may have produced soluble complexes with κ-type anti-factor VIII which retained inhibitory activity.

Table 2. EFFECTS OF ABSORPTION WITH ANTI-κ AND ANTI-λ SERUM

	One stage factor VIII assay: clotting time (sec) Average	Range	No. of determinations
Normal plasma	75	74–75	4
Normal plasma + inhibitor fraction	96	94–99	4
Normal plasma + inhibitor fraction absorbed with anti-κ	84	83–84	4
Normal plasma + inhibitor fraction absorbed with anti-λ	95	93–97	4
Normal plasma + anti-κ	75	74–76	4
Normal plasma + anti-λ	70	—	4

The factor VIII inhibitor in serum G. K. is therefore an antibody of the γG4 sub-class with κ-type light chains. This is consistent with previous observations of physical and chemical characteristics of the inhibitor[2]. A 7*S* sedimentation coefficient, resistance to reduction and alkylation, and decrease in sedimentation coefficient to 3·9*S* with pepsin–cysteine treatment are characteristics of γG-antibodies. Electrophoretic mobility of the inhibitor was faster than the bulk of γG-globulins. γG4-globulins from normal serum and γG4-myeloma are known to have electrophoretic mobilities similar to this inhibitor[6].

Previous investigations have demonstrated antibody activity in the γG1, γG2 and γG3 sub-classes[7]. γG4 sub-class is present in a low concentration in normal serum and has not previously been shown to have antibody activity. The present studies clearly show that γG4 can also possess antibody activity.

Earlier studies[2] failed to demonstrate precipitin reactions, complement fixation and passive cutaneous anaphylaxis. This may have been because there were insufficient concentrations of antigen (factor VIII) or antibody (inhibitor). It is also possible that γG4-antibodies are unable to participate in some or all of these reactions. Studies using γG4-myeloma proteins show that they can sensitize guinea-pig skin for reverse passive cutaneous anaphylaxis[8], but aggregated γG4 in contrast to the other sub-classes does not fix complement[9]. Presumably, γG4-antibodies lack the capacity to fix complement. More observations will be necessary to clarify the biological activities of γG4-antibodies.

Four reported cases have had only γG class inhibitors[1,2] and a fifth was restricted to γA-globulin[10]. Only Poulik's patient[3] had factor VIII inhibitors of mixed classes, γG and γM. In the four cases studied[1,3] only inhibitors with κ-type light chains could be found. In the present study the antibody was not only of one immunoglobulin class, γG, but contained only γG4-heavy chains and κ-type light chains. A similar tendency toward antigenic homogeneity has been observed in cold agglutinating antibodies[11] and erythrocyte auto-antibodies[12]. It has yet to be determined whether the antigen or the nature of the antibody-producing mechanism is responsible for the relative homogeneity of antibodies in these presumably auto-immune processes.

We thank Mrs Judith Cairns for technical assistance. This research was supported by a grant from the US Public Health Service.

Enhancement of Skin Homografts and Dissociation of Immune Responses in Mice immunized with Lyophilized Tissues in Freund's Adjuvant

ATTEMPTS to achieve enhancement of skin homografts in actively or passively immunized animals have so far been unsuccessful, in contrast to the results of experiments with tumour homografts[1-7]. On the other hand, delayed sensitivity can be relatively easily inhibited in adult animals immunized with organ-specific tissue or some defined antigens in saline, or incomplete adjuvant, before sensitization with the same antigens in complete Freund's adjuvant[8-12]. The mechanism of this specific inhibition, which has been called immune deviation[11], and its relation to enhancement or to partial tolerance[12-15], have not been fully elucidated.

Using various schemes of pre-immunization, I have attempted to determine whether transplantation immunity was also effectively inhibited, as judged by the survival of skin homografts exchanged between mice of inbred strains differing at the *H*-2 locus. The results of experiments on *CBA/Jax* mice, immunized with lyophilized spleen cells from *A* strain mice, showed that different degrees of skin homograft enhancement could be achieved according to the dose of lyophilized tissue and the mode and time of its administration. The mode of immunization seemed to be most important in this respect, because a comparison of several experiments (one is illustrated in Fig. 1) revealed that the injection of antigen in incomplete or complete Freund's adjuvant resulted in a longer survival of homografts than immunization with the same or a larger dose of the same antigen in saline. In my experiments, immunization with antigen in incomplete adjuvant was most frequently used because repeated immunization

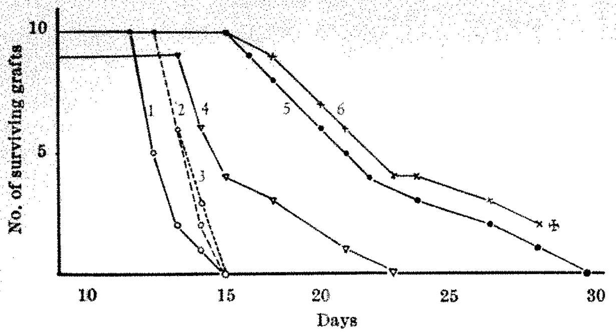

Fig. 1. Dependence on the mode of immunization. All injections were given intraperitoneally. Skin was grafted 6 days after the second injection. 1, Grafts only; $M = 11 \cdot 5$ (11–13). (M . . . Median survival time and the confidence limits with the confidence coefficient greater than 95 per cent.) 2, Incomplete adjuvant three times at intervals of 8 days; $M = 13$ (12–14). 3, Complete adjuvant three times at intervals of 8 days; $M = 13$ (12–14). 4, 6 × 10 mg of lyophilized tissue in saline at intervals of 4 days; $M = 14$ (13–19). 5, 3 × 10 mg of lyophilized tissue in incomplete adjuvant at intervals of 8 days; $M = 19 \cdot 5$ (16–27). 6, 3 × 10 mg of lyophilized tissue in complete adjuvant at intervals of 8 days; $M = 19 \cdot 5$ (16–27).

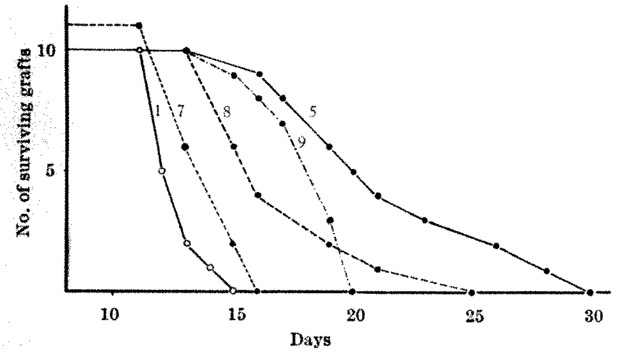

Fig. 2. Dependence on the time of skin grafting. All experimental groups were injected with 3 × 10 mg of lyophilized tissue in incomplete adjuvant at intervals of 8 days. All injections were given intraperitoneally. Skin grafted 6 days after the second injection. 7, Skin grafting 24 h after the first dose; $M = 14$ (12–15). 8, Skin grafting 6 days after the first dose; $M = 15$ (13–20). 9, Skin grafting 6 days after the third dose; $M = 17 \cdot 5$ (15–19).

in complete Freund's adjuvant was accompanied by relatively high mortality.

Most of the *A* strain skin grafts which survived for a prolonged period in experimental mice were completely or partially covered with hair, and their delayed rejection was of a chronic nature, so that they survived for some time with an increasing number of ulcerations. Such grafts were evaluated as positive as long as their epithelium could be distinguished. The ability to reject these grafts was not accompanied by the acquisition of transplantation immunity, because in all nineteen cases where second grafts were applied 14 days after complete rejection of the first grafts, the grafts survived as long as normal first set ones.

Figs. 2 and 3 show that apart from the mode of immunization two additional factors—the time schedule of immunization and dose of antigen—are of decisive importance for the prolongation of skin graft survival. When *CBA/Jax* mice were immunized repeatedly with three doses of lyophilizate from *A* strain spleens (10 mg each) at 8 day intervals before grafting, the prolongation of homograft survival was less pronounced than when skin grafts from *A* strain mice were applied after a second immunization and the third immunizing dose was injected after grafting (Fig. 3). Immunization with only one dose before grafting had a less pronounced effect, and, if the first immunizing dose was given as late as 24 h before grafting, the result was almost undetectable; the survival times of skin grafts in this group did not differ from the values observed in the control group injected with incomplete adjuvant only (Fig. 2). The effect of the dose of antigen on the prolongation of the survival of the skin graft is illustrated in Fig. 3. A two-fold increase of the dose in each individual injection, or the addition of a fourth immunization, prolonged the survival time of the skin graft.

These results agree with the finding that transplantation immunity could not be transferred by regional lymph node cells taken from treated mice. The inhibition of cellular immunity is also accompanied by inhibition of the formation of cytotoxic antibody, as is the case in the prevention of experimental autoimmune aspermatogenesis by injection of antigen in saline before sensitization with complete Freund's adjuvant[16]. No cytotoxic antibodies were detected in sera taken from experimental mice by the seventh day after grafting and as late as the fourteenth day; they were present only in low titres in comparison with control sera (Table 1). On the other hand, the titre of haemagglutinins was higher in the group pre-immunized with lyophilized tissues; this was especially pronounced in sera taken 14 days after grafting (Table 1).

The prolonged survival of skin grafts which occurred in actively immunized mice could be transferred only in part by antisera taken 6 days after a second immunization with lyophilized tissues in incomplete Freund's adjuvant (Fig. 4). A dose of serum, corresponding to 3·3 ml. given in eleven injections within 14 days, resulted in a short but significant prolongation of survival ($P < 0 \cdot 01$). The optimum conditions for passive transfer of enhancement in skin grafts and its dependence on haemagglutinin titre will be reported later.

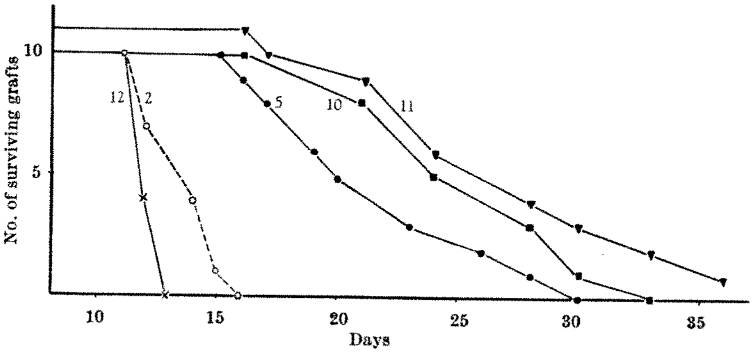

Fig. 3. Dependence on the dose of antigen. All injections were given intraperitoneally. Skin was grafted 6 days after the second injection. 10, 4 × 10 mg of lyophilized tissue in incomplete adjuvant at intervals of 8 days; $M = 25 \cdot 0$ (20–29). 11, 3 × 20 mg of lyophilized tissue in incomplete adjuvant at intervals of 11 days; $M = 24 \cdot 0$ (20–35). 12, Control grafts from *B*10.*D*2 strain; $M = 11 \cdot 0$ (10–12).

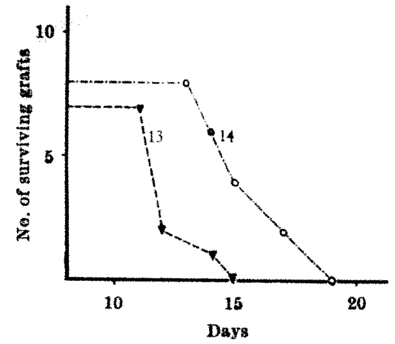

Fig. 4. Passive transfer. Eleven injections of sera, 0·3 ml., each daily (except Sunday). Skin grafting 24 h after the first injection. 13, Control sera from non-immunized mice; $M = 11·0$ (11–12). 14, Immune sera; $M = 14·5$ (13–18).

Prolonged survival of skin grafts after immunization with incomplete and even complete Freund's adjuvant is interesting and agrees with the results of experiments with tumour homografts[17]. In the analysis of the mechanism of this phenomenon, our model has the advantage that the survival of the animals is not endangered by the growth of the graft as is the case with tumour homotransplants.

On the basis of the results obtained in actively and passively immunized mice, it seems that there may be, in addition to antibodies which may be responsible for an afferent or central inhibition, another mechanism which plays a part in the inhibition of transplantation immunity in actively acquired enhancement of skin homografts. If various cell populations are responsible for different types of immune response[18,19], the most probable explanation of this mechanism seems to be a temporarily predominating proliferation of the cell population activated by pre-immunization with lyophilized tissues, and reacting by a harmless or beneficial type of immune response characterized by haemagglutinin formation. On the other hand, a harmful type of immune response leading, in normal conditions, to a rapid destruction of the graft shortly after grafting seems to be temporarily inhibited, perhaps as a result of the competition between immune responses.

I thank Dr P. Iványi for carrying out haemagglutinin titrations and Dr V. Matoušek for statistical analysis.

Immunosuppressive Effects of Lymphoid Cell Proliferation in Mice receiving Anti-lymphocyte Globulin

ANTILYMPHOCYTE serum (ALS) and globulin (ALG) are potent suppressors of certain forms of immune response, particularly homograft rejection[1,2] and the primary antibody response[3]. Their mode of action has, however, been disputed. Although lymphopenia has been considered the essential cause of the immunosuppression[4] it has not always accompanied homograft acceptance which is induced by these agents[2,5]. "Blind-folding" and "sterile blast activation" of lymphocytes by ALG have been proposed as alternative mechanisms[2]. It has also been observed that renal homografts which have escaped rejection can nevertheless be infiltrated by lymphocytes, suggesting that the progeny of lymphoid cells exposed to ALG function inadequately[6].

We have already obtained evidence[7] that ALG ablates circulating blood lymphocytes. We now report that these cells need not necessarily have been functionally replenished even when the absolute blood lymphocyte count had returned to normal after the cessation of ALG injections. Moreover, ALG induces proliferative changes in the lymphoid tissues and indeed this could itself account for the prolonged delay in the return of normal immunological competence. This hypothesis was tested as follows.

Rabbit anti-mouse lymphocyte IgG (ALG) was prepared as previously reported[8]. C_3H mice were given daily intraperitoneal injections (10 mg) for 7 days. Twenty-four hours after the conclusion of these injections, one group of ALG-treated mice was given intravenously 150×10^6 lymphoid cells which were obtained by mixing equal numbers of cells from spleen, lymph nodes and bone marrow from normal C_3H donors. A second ALG-treated group received 10×10^6 peripheral blood lymphocytes which were obtained by the method of Hildemann[9] from the same strain. A third ALG-treated group received no cells, and a control group received 10 mg daily of normal rabbit globulin. All groups were injected intraperitoneally with 1 ml. of 20 per cent sheep erythrocytes on the day of transfer. Haemagglutination titres were determined 6 days later. Table 1 shows that blood lymphocytes restored the capacity of the mice which had been treated with ALG to produce an antibody response, but that cells obtained from lymphoid tissues were ineffective when given immediately after ALG. These findings support the contention that ALG acts primarily on circulating lymphocytes. Indeed the importance of blood borne lymphocytes in the initiation of antibody production by the spleen has recently been emphasized[10].

In order to determine whether the absolute blood lymphocyte count was any guide to the return of immunological competence after a course of ALG injections, we gave groups of twelve C_3H and C57 *Bl* mice daily injections of ALG for 10 days. At the end of this course, their mean absolute blood lymphocyte count was reduced to 500 per cmm but 14 days later the counts had returned to control levels (mean 6,400 per cu.mm). Only feeble haemagglutination titres (mean $\log_2$ titre 1·2) were obtained 6 days after challenge with sheep erythrocytes at this time, however, compared with a mean $\log_2$ titre of 6·0 in control mice.

Table 1. ANTIBODY TITRES TO SHEEP RED CELLS IN C_3H MICE AFTER RECEIVING ANTILYMPHOCYTE GLOBULIN (ALG) AND RECONSTITUTED WITH LYMPHOID CELLS

Group (No. of mice)	$\log_2$ haemagglutination titres at 6 days	Arithmetic mean $\log_2$ titre
ALG only (7)*	0. 0. 0. 0. 0. 0. 0.	0
ALG, then mixed lymphoid cells (7)†	0. 0. 0. 0. 0. 0. 0.	0
ALG, then peripheral blood lymphocytes (7)‡	4. 5. 6. 3. 5. 3. 0.	3·7
Controls (6)	5. 8. 8. 3. 5. 3.	5·3

* ALG in each group given daily for 6 days.

† 150×10^6 mixed lymph node, spleen and bone marrow cells injected intravenously in equal numbers.

‡ 10×10^6 cells injected intravenously.

Cells were given 24 h after ALG and all groups received 1 ml. 20 per cent sheep red blood cells intraperitoneally 24 h after last injection of ALG.

Similar results were obtained in a situation involving a red cell autoantibody. Twenty 2-month old *NZB* mice were injected twice weekly with 10 mg of ALG for 2 months, with resulting lymphopenia (mean 550 lymphocytes/cmm.). Twenty control mice received 10 mg of normal rabbit IgG. Although the absolute blood lymphocyte counts at 10 months of age were identical in the two groups (mean 4,400/cu.mm) all the ALG treated mice had negative antiglobulin tests compared with 80 per cent positive in the controls.

In contrast, although X-irradiation produced lymphocyte depletion of equivalent severity, its immunosuppressive effects were short lived. Thus C_3H mice which were challenged with sheep erythrocytes 14 days after 700 rads produced unimpaired haemagglutinin responses. Similarly, in experiments which are not reported here we have found that the incidence of positive anti-globulin tests at 10 months of age in *NZB* mice which had received 700 rads X-irradiation at 2 months of age does not differ significantly from that in non-irradiated mice.

The more prolonged immunosuppressive action of ALG compared with X-irradiation can be explained by considering the changes in the lymphoid organs which are induced by the former agent. We intravenously injected tritiated thymidine (1·0 μc./g body weight; specific activity 17·8 c./mM) into *C57Bl*, *NZB* and $(NZB \times NZW)\ F_1$ hybrid mice which had received ALG continuously in the same dosage as above for periods of up to 6 months. At 1, 24, 72 and 100 h, autoradiographs were obtained of imprints and sections from the peripheral blood, thymus, spleen, lymph nodes and bone marrow and analysed as described previously[7,8]. The specific activity of the DNA which was isolated from these tissues was measured by liquid scintillation counting[8]. Confirming our observations in rats[7,8], the specific activity of the DNA which was isolated from the lymphoid tissues of mice receiving ALG was significantly higher than that of the DNA obtained from control animals which had received normal rabbit IgG. The results of a typical experiment are shown in Table 2. The values in ALG-treated mice were higher than in the control mice and even exceeded those in the mice which had received X-irradiation, which is known to be followed by a phase of compensatory increase in DNA synthesis[11].

Table 2. INCORPORATION OF TRITIATED THYMIDINE (H^3Tdr) INTO THE LYMPHOID TISSUE DNA OF *NZB* MICE RECEIVING ANTILYMPHOCYTE IMMUNOGLOBULIN G (ALG), OR TOTAL BODY IRRADIATION, AND IN CONTROLS

Group (No. of mice)	Specific activity*		
	Thymus	Spleen	Lymph nodes
ALG treated (4)	34·8 (7·1–96·0)†	28·2 (12·5–40·3)	100·5 (12·8–322·0)
X-irradiated (3)	15·5 (9·8–20·0)	19·7 (18·8–20·2)	4·3 (2·6–6·5)
Controls (5)	2·7 (1·9–4·7)	14·7 (12·2–21·9)	4·8 (3·8–10·3)

ALG group received 10 mg of ALG twice weekly for 4 weeks.

X-irradiated group received 500 rads 3 days before labelling, delivered at 72·0 rads/min (250 kV, 1·2 mm Cu shield).

Controls received normal rabbit gamma globulin twice weekly for 4 weeks.

* C.p.m. per μg of DNA.

† Mean value and range.

The autoradiographs showed that the high specific activity of the DNA in the thymuses and spleens of the ALG-treated mice was attributable, as in similarly treated rats[7], to a striking increase in the numbers of highly labelled reticulum cells and large lymphocytes; these were randomly distributed throughout the cortex and medulla of the thymus and the white pulp of the spleen which was depleted of small lymphocytes. Reticulum cells (reticular lymphoblasts) and large lymphocytes were identified by the criteria of Bessis[12] and Frenkel *et al.*[11].

Furthermore, the high grain counts over these cells in the thymus and spleen fell sharply during the 100 h following labelling, and this fall was accompanied by the appearance after 24 h of labelled small lymphocytes in the thymic cortex and in the white pulp of the spleen. Because small labelled lymphocytes were not seen earlier, they must have arisen from division of labelled precursor cells. It is unlikely that they migrated from the blood, for these mice were still profoundly lymphopenic (< 500 lymphocytes/cu.mm.) and less than 1 per cent of the lymphocytes in their blood was labelled.

The high specific activity of the lymph-node DNA is clearly accounted for by the massive proliferation of plasma cells in the lymph nodes which is known to accompany ALG administration[13].

Levey and Medawar have suggested that an effect of ALG treatment is to produce "sterile activation" of lymphoid cells[14]. The results reported here support this contention, because they show that ALG provokes an intense proliferation of precursor cells leading to the appearance of immunologically incompetent lymphocytes in the circulating blood. Moreover, after ALG treatment, the capacity to make primary antibody responses can only be restored by transfer of peripheral blood lymphocytes from a normal isogeneic donor, and not by non-circulating lymphoid cells from spleen, lymph nodes or marrow. It is certain, however, that lymphocytes are not simply transformed into blast cells by the direct action of ALG as we have induced a blood lymphocytosis of 100,000/cu.mm. in mice by intravenous injection of pertussis vaccine and have then injected ALG. Despite a fall in the blood lymphocyte count to 300 per cu.mm. over a 24 h period, blast cells were not detected in the peripheral blood either morphologically or by tritiated thymidine labelling.

We thank Dr R. H. Mole and Mr M. J. Corp of the MRC Radiobiological Research Unit, Harwell, for help with the irradiation experiment.

Effect of Cyclophosphamide on the Production of Interferon

CYTOTOXIC drugs are widely used for the treatment of malignant disease. Many of these agents are also powerful immunosuppressants, affecting both humoral and cellular immunity. Other antiviral defence mechanisms can also be affected by cytotoxic drygs; for example, the production of interferon can be depressed by actinomycin[1,2] and puromycin[3]. Steroids have also been shown to suppress the production of interferon[4].

We describe here experiments which show that cyclophosphamide depresses interferon in the intact animal but is without activity in tissue culture systems.

Preliminary experiments indicated that 1 mg/ml. of cyclophosphamide was not toxic for cultured monkey kidney cells. It was also shown that this concentration of the drug had no effect on the growth of the Sendai strain of parainfluenza and the Kunz strain of influenza *A* virus in the same cells. These findings suggested that cyclophosphamide was having no effect on normal metabolic processes of the cell, the processes concerned

5	400	44	< 8
6	200	39	< 8
7	200	96	26

Assays were carried out on lungs removed on either the third or fifth day after infection.

with viral replication, and probably no effect on the processes concerned with the production of interferon.

The effect of cyclophosphamide on the production of interferon in tissue culture was determined directly, using the method of Paucker[5] in which interferon is induced in mouse *L* cells by Newcastle Disease Virus. Cyclophosphamide was incorporated in the tissue culture medium of the experimental cultures in a concentration of 1 mg/ml. and interferon was assayed by the quantitative haemadsorption method[6]. The results of three experiments are shown in Table 1, which demonstrates that cyclophosphamide had no effect on the yields of interferon.

In contrast, cyclophosphamide treatment consistently depressed the production of interferon in the intact animal. Swiss white mice were inoculated intranasally with $10^{5.5}EID_{50}$ of Sendai virus. The mice were killed and exsanguinated on either the third or fifth day after infection and their lungs were processed and assayed for interferon. Animals were inoculated subcutaneously with cyclophosphamide as indicated in Table 2, which shows the results of seven experiments with different batches of mice. Although there was considerable variation in the amounts of interferon produced in the different experiments, the titres were always considerably lower in the cyclophosphamide treated animals.

The difference between the *in vitro* and *in vivo* effects of cyclophosphamide on the production of interferon can be explained if certain metabolic processes of the intact animal are required to convert the drug into its active form[7]. This lack of activity in tissue culture has also been observed by Hampel *et al.*[8], who have shown that cyclophosphamide (in contrast to most cytotoxic drugs) does not damage the chromosomes of lymphocytes cultured *in vitro*, but chromosome damage can be demonstrated if these cells are treated with the serum from rats treated with cyclophosphamide.

These findings show that cyclophosphamide, like many other cytotoxic compounds, may adversely affect not only immune processes but also certain non-specific reactions concerned with defence against viral infections.

We thank Messrs Ward, Blenkinsop and Co., Ltd., for the cyclophosphamide, and Miss G. V. Martin for technical assistance.

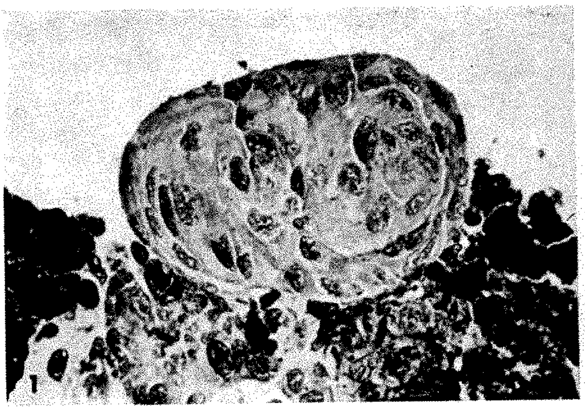
CYTOLOGY

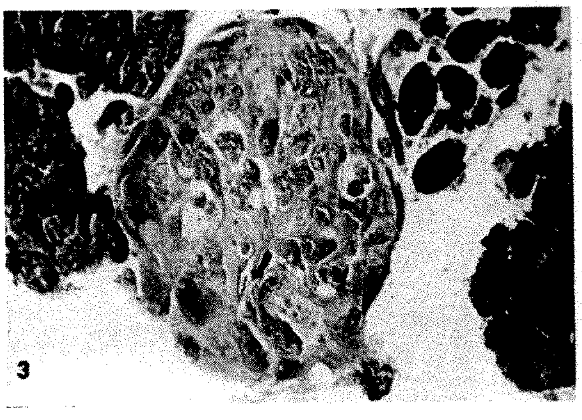
In vitro Culture of the Regenerating Lens

LENS regeneration by the dorsal iris in the lentectomized newt is a phenomenon which has been studied from the viewpoints of experimental embryology[1,2] as well as cell biology[3-7]. Most of the studies so far reported, however, have been performed *in vivo*. The potential advantages of performing such studies in controlled conditions led us to develop an *in vitro* method for the culture of the regenerating lens of the newt *Triturus viridescens*.

The technique involved placing the lens regenerates on agar cubes into which culture medium had been incorporated. The two media used were medium 199 with 15 per cent foetal bovine serum or Puck's *N*-16 (Microbiological Associates, Bethesda, Maryland). Penicillin was added at a concentration of 200 U/ml. The agar blocks were prepared by mixing either of these media with 4 per cent aqueous agar (noble Difco agar) solution 1 : 1 by volume and pouring into a 5 cm Petri dish to a depth of about 3 mm. After solidification, cubes of approximately 5 × 5 × 3 mm were cut out. These were placed into 3 cm tissue culture Petri dishes which had previously been filled with culture medium without agar up to a depth of 1 to 2 mm. The agar substrate was used to inhibit the outgrowth of cells from the regenerate, and the additional liquid medium was used to saturate the culture with nutrient solution.

The dorsal iris with the regenerating lens was dissected from the eye of the lentectomized newt in aseptic conditions, washed with Earle's balanced salt solution and placed on the surface of the agar block. The cultures were incubated at 25° C in 5 per cent carbon dioxide and





Figs. 1 and 3. 20 day old regenerates cultured for 5 days in Puck's medium *N*-16. Lens fibres are conspicuous and squamous cells are present at the periphery of the regenerates.

90 per cent relative humidity. Maintenance of the *p*H of the culture between 7 and 7·4 with a carbon dioxide atmosphere was essential for optimal development of the regenerates. Cultures, in which alkalinity developed, died or survived in a poor condition.

Regenerates at day 9, 15 and 20 after lens removal were cultured for 5, 7 and 10 days. Mitoses were seen in pigmented and depigmented cells and the differentiation of cells into fibres continued (Figs. 1, 3, 4, 5 and 6) as compared with controls (Fig. 2). Both culture media were suitable for developing the tissue; however, a better differentiation was observed when the medium with serum supplement was used.

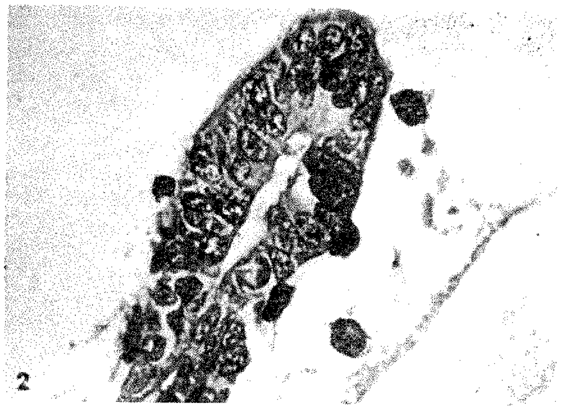


Fig. 2. Control for regenerate in Fig. 1. Both eyes were lentectomized in the same animal. This regenerate was fixed at the same time that regenerate in Fig. 1 was started in culture.

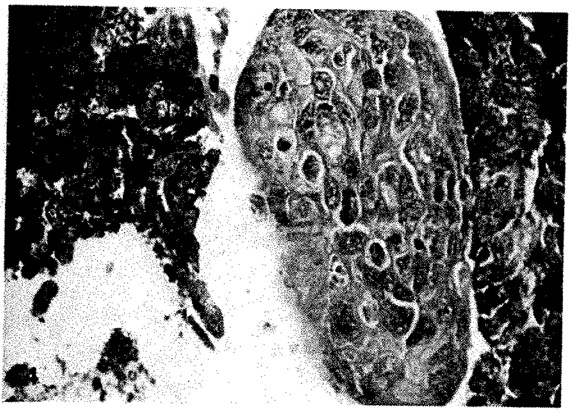

Fig. 4. 20 day old regenerate cultured for 10 days in medium 199 plus 15 per cent foetal bovine serum.

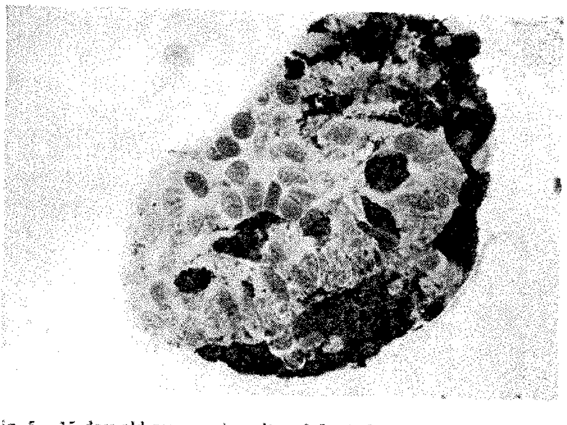

Fig. 5. 15 day old regenerate cultured for 7 days in medium 199 plus 15 per cent foetal bovine serum. Observe elongation of cells into fibres.

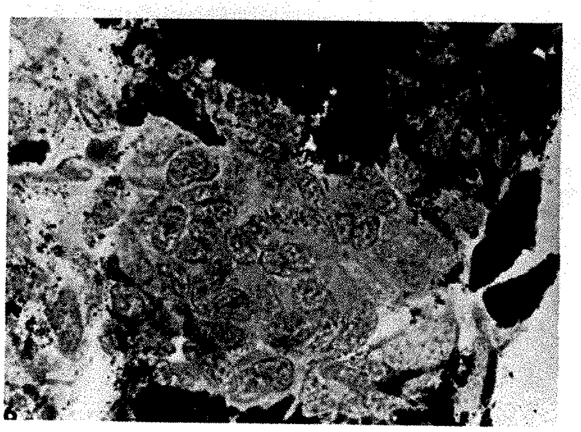

Fig. 6. 9 day old regenerate cultured for 7 days in medium 199 plus 15 per cent foetal bovine serum.

An interesting feature in the cultured regenerates was the disappearance of the presumptive lens epithelium. It seems that cells in this region of the lens regenerate elongated and form lens fibres (Figs. 3, 4 and 5) or become transformed to squamous type cells surrounding the developing lens (Figs. 1 and 3).

Our experiments suggest that as early as 9 days after lentectomy, the lens regenerate, can survive *in vitro* conditions and continue with further differentiation. The results on the further progress of differentiation *in vitro* from day 9 of regeneration onwards agree with the preliminary results of Reese (reported by Yamada[8]). In other studies, we have found that in these conditions the integrity of the cultured regenerates was maintained and the cells remained healthy for periods of up to 30 days. A more detailed study in the differentiative capacities of developing lenses at successive stages of regeneration is being performed.

This work was supported in part by a grant from the National Research Council of Canada. We thank Mrs V. Scott for technical assistance.

Effect of Cell Cycle on Recovery from Radiation Damage in the Mouse Liver

I HAVE studied the chromosomal aberrations which are induced in mouse hepatocytes by single and fractionated doses of X-rays given at various times before or after surgical partial hepatectomy. The data presented here show that the different phases of the cell cycle possibly differ not only in their sensitivity to chromosomal damage by radiation but also in their ability to recover from such damage.

Female *SAS*/4 mice 12 weeks old which had been anaesthetized with sodium pentobarbitone ('Nembutal'), 60 mg/kg body weight, were partially hepatectomized to remove two-thirds of the liver[1]. The surgery was performed so that subsequent killing, 66 h later, by cervical dislocation was always between 9.00–10.00 a.m., thus offsetting possible diurnal mitotic rhythm which has been reported to occur[2]. The remaining regenerating liver was excised and sections 5μ thick were stained with haematoxylin and eosin for microscopic examination. Similar anatomical areas of the anterior right lateral lobe were scanned in each mouse by one investigator using coded slides to score chromosomal abnormalities. The aberrations, bridges and fragments were scored in 100 anaphase/telophase figures in each liver, using approximately ten mice in each group. Irradiation was carried out with a 250 kVp, 15 mamp X-ray machine, filtered so as to give a dose rate of 105 rad/min at 30 cm focal spot distance. The filtration was 1 mm Al inherent and a 'Thoraeus II' filter which gave uniform beam over the field was used. Mice, which were unanaesthetized, breathing air, and which were constrained in a 'Perspex' tube with walls 0.5 cm thick, were irradiated, two at a time.

The upper curve in Fig. 1 is a plot of the logarithm of the fraction of normal mitoses against dose for cells exposed 24 h before partial hepatectomy, that is, while in the G_0 phase. The values which are plotted are relative to those in non-irradiated mice for which 94.5±0.7 per cent of normal mitoses was observed. There is a close fit to an exponential function with a fitted line drawn through all points having a $D_0 = 1{,}228 \pm 31$ rads and an extrapolation number of 1.00±0.02. The lower curve in Fig. 1 shows the same effect for irradiation which was given 24 h after partial hepatectomy when the regenerating cells were, as has been shown by autoradiography in this laboratory, to be in G_1 or early *S*. This line has a definite curvature and a fitted line on the last four points gives a $D_0 = 300$ rads and an extrapolation number of 6.7. There is thus a very large difference in radiation sensitivity, as far as chromosomal damage is concerned, between cells irradiated in the G_0 phase or early *S* phase. Furthermore, in the latter case, the curve has a pronounced shoulder which is indicative of repair of damage, while the upper curve has no shoulder.

In order to test whether a difference in ability to recover was detectable between G_0 cells and cells in G_1/S, fractionation experiments were carried out. The lower curve of Fig. 2 shows the relative proportion of normal mitoses which were observed after splitting a dose of 950 rads into two equal fractions, the first fraction being given at 24 h before partial hepatectomy and the second being given at the times shown—that is, 3, 9, 16, 21, 24 h later—right up to the time of the operation. There seems to be no significant difference in chromosomal damage between the single and the split dose over the 24 h period which was studied. Such a result suggests that no recovery of chromosome damage occurs in G_0 cells during 24 h. In contrast, the upper curve shows the increased proportion of normal mitoses, interpreted as "recovery", which takes place by splitting the same dose and giving the first half 24 h after partial hepatectomy and the second half at the times shown. Further experiments in this laboratory have shown that the reduced yield of aberrations which was observed was not caused by the second fraction of the dose being given to cells in a phase of increased radioresistance.

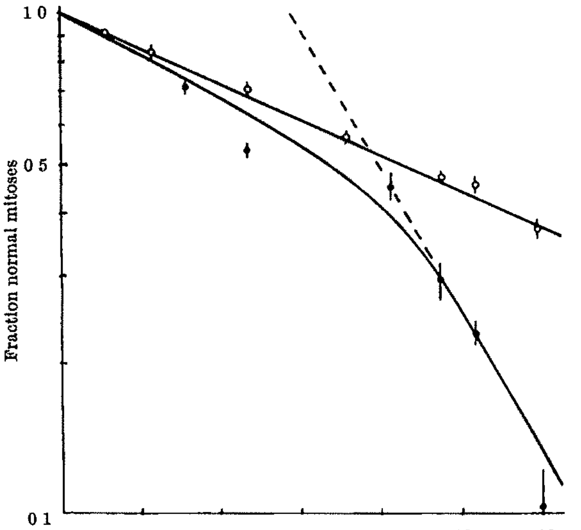

Fig. 1. A plot of the logarithm of fraction normal mitotic figures against doses of X-rays. ○, Doses given 24 h before partial hepatectomy; ●, Doses given 24 h after partial hepatectomy. More points would be desirable for the latter fitted line; this is, however, technically very difficult.

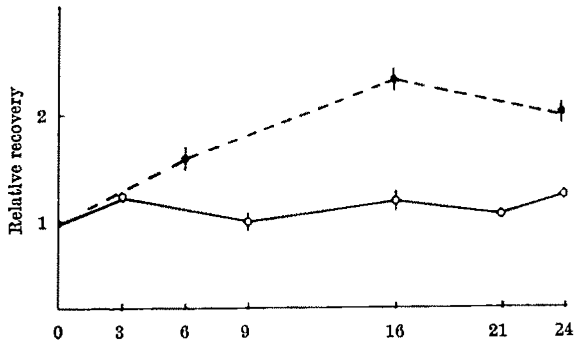

Fig. 2. Relative recovery factor for chromosomal damage induced by radiation against time between two fractions of 475 rads each. ●, Doses given after partial hepatectomy; ○, doses given before partial hepatectomy.

The percentage yields of chromosomal damage for G_0 cells (Fig. 1) are in accord with published values[3-7] although these authors used only one or two doses. The greater sensitivity of cells in actively dividing liver is in agreement with Albert[3]. The reasons for the difference in sensitivity remain obscure, but an oxygen effect could be involved because in regenerating liver an inflammatory reaction exists and increased oxygenation possibly results in increased sensitivity. Cater (see Holmes[8]), however, reported a 40 per cent increase in the consumption of oxygen in regenerating liver slices relative to that in normal liver; the tissues are therefore unlikely to be highly oxygenated unless there is a correspondingly greater oxygen supply, for which there is no evidence. Alternatively, increased sensitivity could be a result of the difference between time of irradiation and the time of assay of the damage, because in each case the latter was 66 h postoperatively and there was therefore a difference of 48 h between irradiation and assay times of cells irradiated 24 h before (G_0) and those irradiated 24 h after (G_1/S cells). Greater damage might be expected in the latter because they had less time available for any repair. The slight increase in damage which was observed for the 16 h split dose compared with that at 24 h, in the upper curve of Fig. 1, however, argues against this interpretation.

The lack of recovery in G_0 cells which were exposed to split doses is in agreement with Shapiro[5], who reported no sparing effect when two doses were split by a 7 day period. Several papers[3-7] report little or no decrease in the number of abnormalities when partial hepatectomies were performed many weeks or months after a single dose of radiation, and only one[7] noticed a decay in the proportion of "bridges" but not in overall percentage abnormalities. In contrast, two workers[9,10] showed chronic irradiation to be less effective than acute exposures; this is suggestive of repair, as one of the workers[9] excludes cell death at cell division as a factor lessening observed damage. The persistence of chromosomal abnormalities which were found in peripheral blood cultures[11] could represent another example of the lack of recovery in cells which were not actively in cell cycle.

There does seem to be a recovery, however, when split doses are given after partial hepatectomy. The upper curve in Fig. 2 shows a smooth early recovery with no evidence of fluctuations in recovery pattern as have recently been reported[12], although split doses separated by less than 6 h might reveal such patterns.

It might be suggested that the population feedback mechanism which keeps cells in G_0 (ref. 13) also inhibits the metabolic pathway necessary for repair of damage, as seen in cells which are in cycle. This might constitute a definitive characteristic of the G_0 phase.

PHYSIOLOGY

Iodine Compounds in Plasma of Rats: Effect of Exposure to High Environmental Temperature

THE rate of release of iodine-131 from the thyroid has been widely used as an index for thyroid activity and has been considered a reliable index for thyroid function[1]. It is also used as a basis for the rate of secretion of thyroxine (TSR) by the replacement method[2]. Recently, this laboratory[3] reported a higher rate of release of iodine-131 from the thyroid in rats following long-term exposure to a high environmental temperature (34° C). These findings prompted the question whether the composition of the substance(s) released might be constant in different physiological conditions, that is, would long-term exposure to environmental heat alter the composition of the iodinated compounds which were released by the thyroid gland? This experiment was undertaken in order to determine the nature of the iodinated compounds in plasma of rats during exposure to heat (34° C).

A group of fifty-six male rats of the Holtzmann strain (3 weeks old) was maintained in a climatic chamber at 28° C and 50 per cent relative humidity (RH). At the age of 6 weeks, twenty-four rats were exposed to a constant temperature of 34° C and 50 per cent RH and were maintained in these conditions for more than 20 weeks. Carrier-free iodine-131 was diluted in distilled water to contain 20 μc./ml. and 0.5 ml. was administered intraperitoneally to the rats. Twenty-four hours after the injection of iodine-131 blood samples (2–3 ml.) were collected by heart puncture from each rat. Blood samples were collected after 1, 3, 6, 12 and 20 weeks' exposure to heat (34° C). Rats which were maintained at 28° C were bled at the beginning and at the end of the experiment.

The iodine-131 compounds in plasma were separated using a descending chromatographic technique described by Heninger *et al.*[4]. The iodine-131 activity was assayed in a well type scintillation crystal detector.

Fig. 1 illustrates the percentage of iodinated compounds in the plasma of rats which were raised at 28° C and of others which were exposed to high temperature (34° C) for 1, 3, 6, 12 and 20 weeks. The triiodothyronine (T_3) and diiodothyronine (T_2) fractions were not adequately separated and the radioactivity of both fractions was therefore combined. The results at 28° C and 34° C indicate that thyroxine (T_4) contains most of the iodine-131 compounds in plasma. At 28° C, the rat plasma contains an average of 93.5 per cent T_4, 4.6 per cent $T_2 + T_3$, 0.6 per cent monoiodotyrosine (MIT) and 1.6 per cent inorganic iodine (I^-).

After exposure to heat at 34° C the iodine-131 compounds in plasma were not significantly different from the values which were obtained at 28° C after exposure for 1 and 3 weeks. After 6 weeks of exposure to 34° C the composition of the iodine-131 compounds was significantly ($P < 0.05$) different from the values which were obtained for these compounds at 28° C. The T_4 fraction was decreased and the I^-, MIT and $T_2 + T_3$ fractions were increased. After exposure for 12 and 20 weeks at 34° C the T_4 fraction was significantly lower ($P < 0.01$) than the values at 28° C. These data suggested a significant effect of long-term (at least 6–12 weeks) exposure to heat on the composition of iodine-131 compounds in plasma (Fig. 1).

The results which are presented confirmed that T_4 is the principal iodine-131 compound in the plasma of rat. Pitt-Rivers and Rall[5] reported 92–94 per cent T_4, 4.2–4.4 per cent T_3 and 1.3–3.4 per cent iodinated thyronines (MIT + DIT) in rat plasma. Laidlaw[6], however, found that in a few rats (three animals), plasma contained 60 per cent T_4, 48 h after the injection of iodine-131. The uniqueness of the data shown in Fig. 1 is the change which occurred in the iodine-131 compounds in the

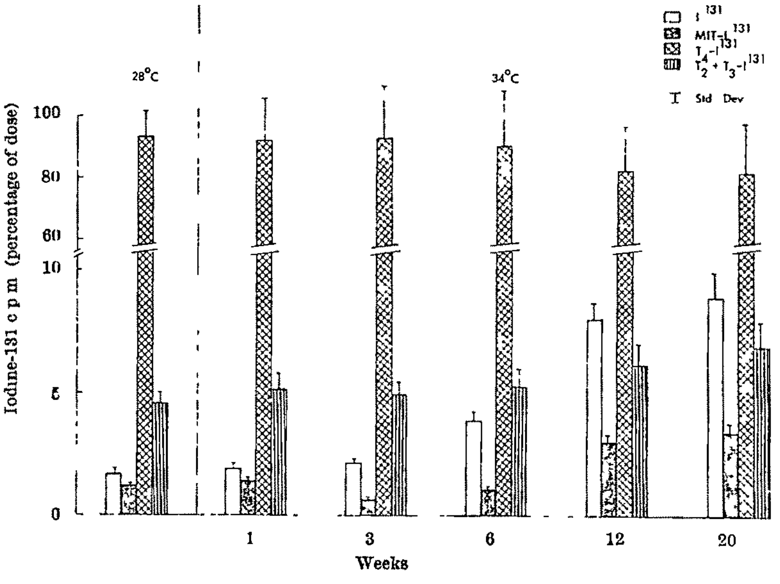

Fig. 1. Changes in iodinated compounds in plasma during long term exposure to heat (34° C).

plasma of rats which were exposed to 34° C. The data suggested that the composition of the thyroid secretion changes during acclimatization to heat (34° C) For example, the ratio of I^- T_4 changes from 1 55 at 28° C to 1 23, 1 10 and 1 . 9 at 34° C after exposure for 6, 12 and 20 weeks, respectively. The ratio of MIT $T_2 + T_3$ changed from 13 100 to 21 100, 51 100 and 49 100 at 34° C for 6, 12, and 20 weeks, respectively

To explain the changes which occurred in the composition of the iodinated compounds during heat acclimatization, there are three possibilities (*a*) perhaps the heat affects the permeability of thyroid cells resulting in the cellular release of more I^-, MIT and less T_4; (*b*) the heat could affect the acinar cellular processes which limit the biosynthesis of T_4, (*c*) changes in the percentage of I^- in plasma of rats which were exposed to heat could reflect either a reduction in renal clearance of I^- or a reduced uptake of iodine-131 by the thyroid, or both Details of body weight and other physiological functions at 34° C are reported elsewhere[7]

Knowing that the release rate technique measures the rate of all the iodine that comes out of the gland/unit of time, any changes in the composition of the iodine which is released from the gland are ignored by this technique and may mask the true secretory action of the thyroid gland Results obtained by the release rate technique should be explained with great caution when the animal is deviated from its thermoneutral environment and exposed to high or other ambient temperature conditions

Regeneration of a Peripheral Nerve Implant into Goldfish Telencephalic Parenchyma

THE nerve fibres of a peripheral nerve implanted in the cortex of the rat[1] or cat[2,3] do not regenerate into the brain parenchyma The glial scar which lines the wound made in the parenchyma during nerve implantation seems to be a mechanical barrier to successful regeneration After nerve implantation and administration of the drug piromen, however, the peripheral axons which formerly had not grown through the glial scar now grow through the scar[2,3]

Several chemical agents have induced the growth of axons in the central nervous system, which demonstrated that the effect of the glial scar which seems to be a barrier in the normal course of regeneration can be negated[2-4]. In the goldfish, a glial-ependymal scar was observed after central nervous system insult This scar does not act as a mechanical barrier to regenerating axons of the central nervous system[5,6] The present experiments were undertaken to ascertain the tissue reaction of the telencephalon of the goldfish to an implanted peripheral nerve

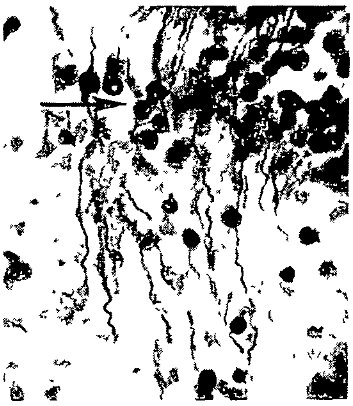

Fig 1 The peripheral nerve fibres regenerated through a dense glial-ependymal scar (arrow) into the telencephalic parenchyma. Silver stain (protargol, × 850)

Seven goldfish (*Carrasius auratus*) 3–6 yr old and approximately 17 cm long were used in these experiments The goldfish were anaesthetized with Tricaine methanesulphonate ('MS-222', Sandoz, 1 4,000) The cranium was opened with a trephine and the fatty substance surrounding the brain aspirated On the floor of the cranium a branch of the seventh nerve within the cranial cavity was exposed This nerve was dissected free, turned and implanted into a stab wound within the telencephalon A cap was used to close the cranium Animals were killed 90 days later and the degree of regeneration was assessed

Five animals were perfused with 10 per cent isotonic formol-saline, the brain removed, dehydrated, embedded in paraplast and sectioned at 10μ Alternate sections were stained with silver ('Protargol'), or with periodic acid–Schiff's reagent and haematoxylin Two animals were perfused with 2 5 per cent gluteraldehyde in a phosphate buffer (*p*H 7 4). The telencephalon with the implant was removed, washed in buffer and placed in buffered 2 per cent osmic acid for 2 h The tissue was then dehydrated and embedded in 'Araldite' Sections 1μ thick were stained with methylene blue, Azure II or toluidine blue

Although the stab wound in the telencephalon resulted in the formation of a glial-ependymal scar, the peripheral nerve fibres regenerated into the brain parenchyma (Fig 1) The glial-ependymal scar was from two to seven cells thick and was characterized by long interdigitating cytoplasmic processes of the cells constituting the scar The peripheral nerve fibres seemed to grow between these cellular processes and splay out into the brain parenchyma The nerve fibres did not grow as compact bundles of nerve fibres, but were discrete axons that grew between the glial, ependymal and neuronal cell processes The peripheral nerve fibres seemed normal when compared with cells of the contralateral unoperated telencephalic hemisphere

After administration of the drug piromen peripheral nerve fibres which usually do not grow into the brain parenchyma will successfully regenerate into the cortex of cats This phenomenon has been interpreted as the loosening of the glial scar allowing for the penetration of the nerve fibres[2,3] Recent evidence has demonstrated that except for the synaptic bed of Mauthner's cell[7] the extracellular space of the fish brain does not seem to differ from that of the mammalian brain[8] These data seem to demonstrate that the glial-ependymal scar of the goldfish, through which the peripheral nerves regenerated, is not morphologically more loose than the mammalian glial scar through which peripheral nerves do not regenerate The regeneration of axons in the mammalian nervous system seems to depend on the establishment of proper milieu for nerve regrowth This has been demonstrated by the fact that axons of the mammalian brain stem and spinal cord will resume growth (sprout) after partial denervation of the neurones in the surrounding parenchyma[8] The action of piromen could therefore be considered to induce a change in the permeability of the cellular constitution of the glial scar, thus creating a proper environment for the growth of the peripheral nerve fibres through the scar The chemical constituents of the telencephalon of the goldfish are such that a proper milieu is established within the brain parenchyma allowing for the successful regeneration of peripheral axons, whereas drugs or special operative procedures must be utilized in the mammalian brain to induce the proper neurotrophic environment

Regional Distribution of Tritiated Acetylcholine in Rat Brain

THE almost universal occurrence of acetylcholine, other choline derivatives and cholinesterase in the vertebrate nervous system, and effects of cholinesterase inhibitors on the central nervous system have suggested that cholinergic systems play an important part in brain function The experimental evidence for such a role ranges from effects on the rate of discharge of single brain neurones to complex animal behaviour[1] Whittaker[2] has demonstrated that acetylcholine is located primarily in the specific tissue fraction consisting chiefly of nerve ending particles De Robertis[3] has located acetylcholine in the synaptic vesicles recovered from brain homogenates

Recent studies have demonstrated that ^{3}H-norepinephrine introduced into the brain by intraventricular injection is taken up by neurones which contain catecholamine, where it mixes with the endogenous norepinephrine stores[4] We therefore thought it of interest to determine whether ^{3}H-acetylcholine can also be accumulated in the brain in analogous fashion Because acetylcholine is reported to occur unequally in various regions of the brain[1], regional distribution of injected ^{3}H-acetylcholine was determined with the hope that differences in distribution among various brain regions may reflect the relative importance of this compound in these regions. Because intravenously injected acetylcholine does not readily penetrate the blood–brain barrier, ^{3}H-acetylcholine was administered into the lateral ventricle of the brain. (The acetylcholine was purchased from New England Nuclear Corporation, who state that the labelling is in the methyl group of the acetyl The correct designation should therefore be acetyl-^{3}H choline According to New England Nuclear Corporation and Nuclear-Chicago, tritiated acetylcholine, labelled either in the acetyl or *N*-methyl groups, has the biological and chemical properties of "cold" acetylcholine)

Female Sprague–Dawley rats weighing 180–200 g were anaesthetized with ether and fixed in a stereotaxic device A hole just large enough to accommodate a 27 gauge needle was drilled through the skull on the coronal suture 1 5 mm lateral to the bregma A polyethylene sleeve was fitted to penetrate 4 mm below the surface of the skull Penetration to this depth placed the tip of the needle in the lateral ventricle This was verified by dissection of fresh brains after the injection of indian ink Physostigmine hydrochloride (1 mg/kg) was injected subcutaneously 5–10 min before the injection of acetyl-^{3}H choline into the ventricle in order to inhibit hydrolysis of the administered acetylcholine Acetyl-^{3}H choline (5 μc 4 2 mg/mc) was drawn into a 50 μl Hamilton syringe fitted with the 27 gauge needle described here and injected into the lateral ventricle After 5 sec, the needle was withdrawn and the hole covered with the index finger to prevent leakage The animals were decapitated 30 min after injection of the acetyl-^{3}H choline. The brains were removed immediately and rinsed in cold 0 9 per cent sodium chloride They were then dissected in cold saline into nine regions Each brain portion was blotted, weighed and homogenized in 4–10 ml of cold 0 4 normal perchloric acid, according to the method of Hebb *et al* [5] After centrifugation, a 1 ml aliquot of the supernatant fluid was transferred to 10 ml of Bray's solution Total radioactivity was measured by means of a Nuclear Chicago liquid scintillation counter

Our results indicate that acetyl-^{3}H choline accumulated in the brain tissue The rate of disappearance of radioactivity from the whole brain was relatively rapid with reduction within 30 min to half the activity that was present at 2 min (Fig 1) If true uptake of the acetyl-^{3}H choline into the physiological pool of endogenous acetylcholine is assumed, our results indicate a rather rapid turnover of acetylcholine in the rat brain Analysis of various regions of the rat brain indicates (Table 1) that acetyl-^{3}H choline was not taken up equally The differences in uptake among some regions were highly significant We have included data on the occurrence of endogenous acetylcholine in Table 1 in order to enable comparison with the distribution of acetyl-^{3}H choline No data on the occurrence of endogenous acetylcholine in the hippocampus and diencephalon are available for comparison with our finding that the greatest accumulation of acetyl-^{3}H choline occurred in these regions The basal ganglia, where Votava[1] found considerable concen-

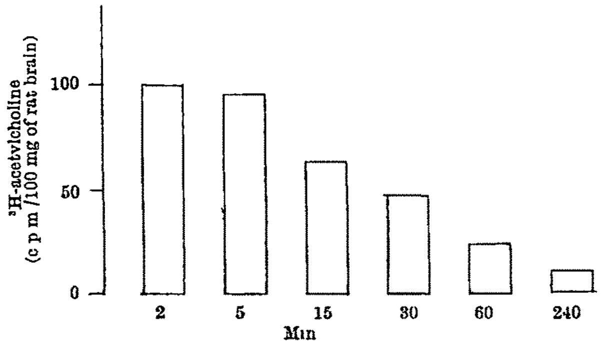

Fig 1 Rate of disappearance of acetyl-³H choline from the whole brain of rats Each point represents the mean of results in three rats each injected with 5 μc of acetyl-³H choline and decapitated at the times indicated on the abscissa

tration of acetylcholine, accumulated relatively large concentrations of acetyl-³H choline The observation by Votava that the cerebral cortex had more acetylcholine than did the basal ganglia cannot be compared with ours because the cerebral hemispheres we analysed included other telencephalic structures We found that the mesencephalon accumulated about 44 per cent as much acetyl-³H choline as the basal ganglia which is lower than the 95 per cent endogenous acetylcholine reported by Votava We are unable to account for these differences.

Although this study indicates that the brain takes up acetyl-³H choline, it is not yet possible to decide whether this is of physiological significance Passive uptake of ¹⁴C-acetylcholine by the mitochondrial, pinch-off nerve terminal, and synaptic vesicle fractions in rat brain[6] has been demonstrated The marked and consistent differences in regional distribution in our experiments suggest that the differential accumulation of acetyl-³H choline in various brain regions is not fortuitous, and may reflect the degree of involvement of acetylcholine in the activity of these regions

Human Rod Visual Delay

In 1922, Pulfrich[1] noticed that when a swinging pendulum bob is viewed binocularly with a neutral density filter over one eye the bob appears to describe an ellipse The effect is caused by the extra delay associated with the lower illumination level in the filtered eye (Fig 1) This promoted interest in finding the relation between visual delay and intensity

Variations of visual delay with intensity have been measured electrophysiologically[2,3] It has been shown for animals that, whereas the total visual delay depends on the measuring point along the optic pathway, its variation with the intensity of stimulus is everywhere the same.

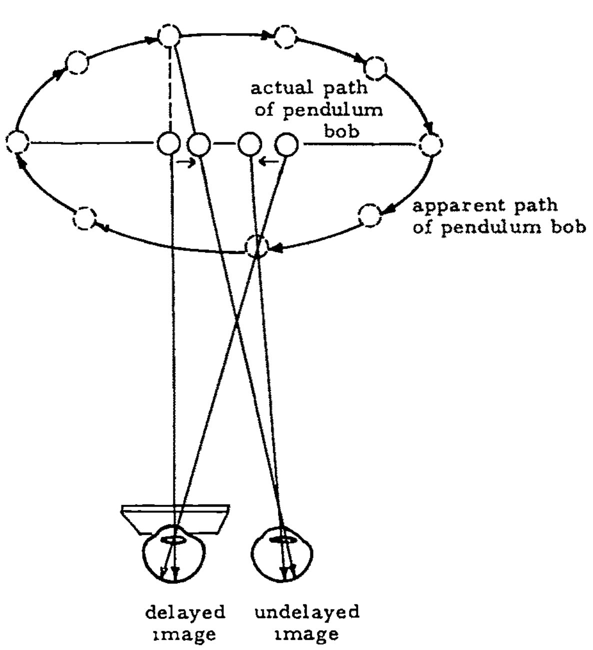

Fig 1 The Pulfrich pendulum for gaze centred straight ahead (Adapted from Gregory[7])

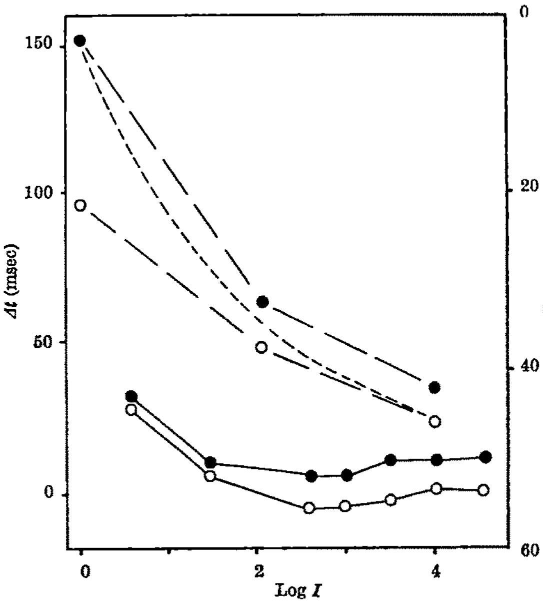

Fig 2 Delay versus intensity curves for rod vision obtained by Arden and Weale Their caption The change in the latent period of vision with intensity Ordinates on the left Δt in msec, on the right, degrees of episcotister scale Abscissa the logarithmic intensity scale expressed in multiples of the absolute threshold of vision, as measured with a 3 min field at 8° in the right visual field of the left eye ●, Observer G B A , ○, R A W Continuous line, foveal data, broken line, extra-foveal data, dashed curve, Bernhard's data (For details see text)

Thus variations must take place in the retina peripheral where all electrophysiological measurements have been made In 1954, Arden and Weale[4] measured human rod visual delay versus intensity by flashing a 3 min field for 3 msec at 8° off the centre of gaze Their methods relied on subjective reporting of simultaneity between two flashes Fig 2 shows that they agree well, however, with Bernhard, who arrived at his results by relating human EEG blocking times to stimulus intensities Weale[5] and Bornschein[6] had earlier verified that rods were active in photopic conditions, and that rod activity can be suppressed only at the highest levels of luminance So Arden and Weale further investigated the Pulfrich

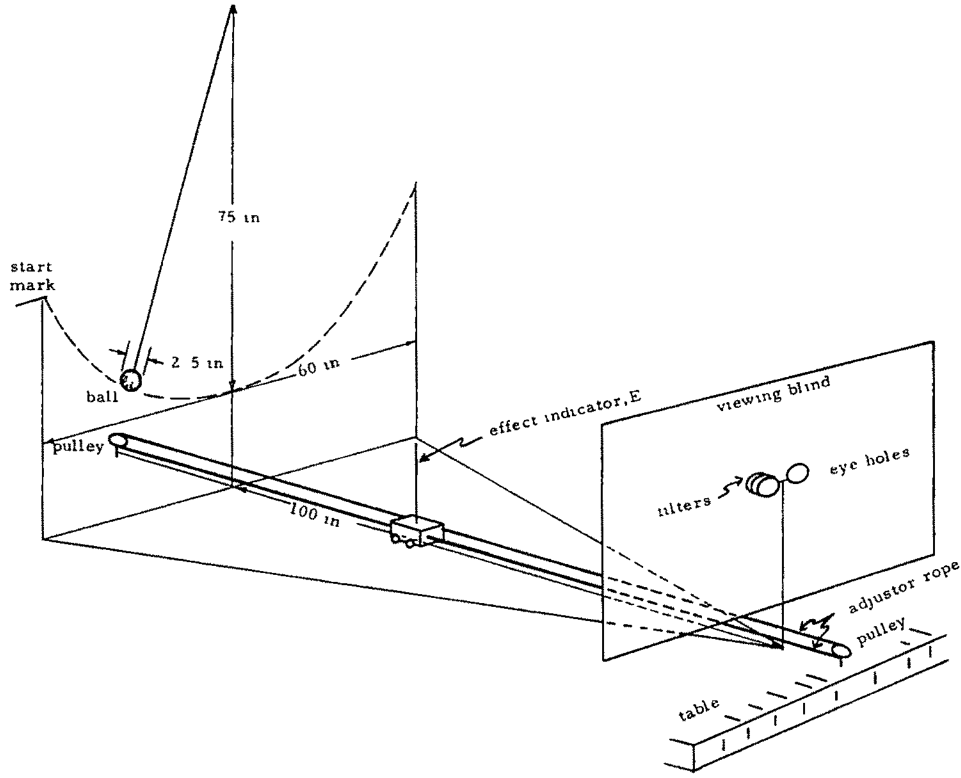

Fig. 3. Experimental apparatus

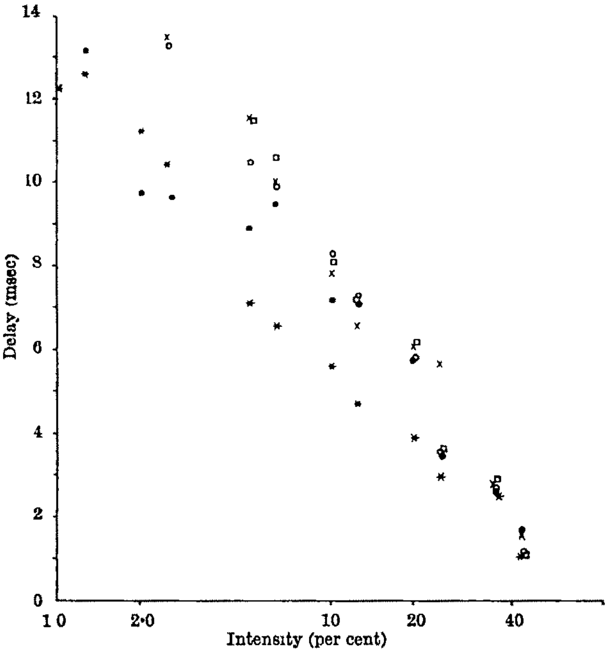

Fig. 4. Delay versus percentage of right eye light intensity admitted to left eye for five subjects. O, Mo; ×, Jane; □, Nancy; ●, Pam; *, Jeff

pendulum effect using only the shapes of their rod and cone delay curves and coloured eye filters. They concluded that the effect was predominantly the result of rod vision. They tacitly assumed that the curve of rod vision delay-versus-intensity is the same in natural visual conditions as it is for dark adapted eyes looking at 3 min spots for 3 msec in a darkened room. The multifarious effects of lateral inhibition in the retina[7-10] would seem to dictate against this unless variations in rod visual delay are wholly mediated within the rod receptor layer. We decided to use the Pulfrich pendulum to check this possibility.

Our experimental set-up is shown in Fig. 3. The 1·4° bright blue ball had a swing period of 2·9 sec and was boosted back to the start mark by an experimenter every three swings. The subject was asked to focus on the effect indicator, *E*, and by means of the adjustor ropes, to move *E* until it appeared to be just under the nearest point of the ball's apparent trajectory. This assured rod vision results. The experiment room was a small classroom, and was lit during each test by fluorescent overhead lights and early afternoon sunlight through windows to the left of and behind the ball. The illumination level was about 40 ft.-candles so, according to Rushton[11], our well adapted subjects had equilibrated at about 10 per cent rhodopsin bleach. Each subject performed an *E* alignment for each case over a random sequence of neutral density filter strengths. The tests on each subject were repeated several times during several days with the usual precautions. All subjects were between 20 and 40 yr old. The greatest effect was obtained with Nancy, who set *E* at 40″ on her side of the pendulum plane with a 320 reducing filter. At the point of fastest movement of the ball image on the retina, the image covered each rod for more than 20 msec. The ball image definitely produced an "on" effect in an otherwise static visual field filled with a variety of textures, colours and forms.

Our results are shown in Fig. 4. If percentage intensity were plotted on a linear instead of logarithmic scale, the shape of our curves would approximate Arden and Weale's, and Bernhard's. We must therefore conclude that the rod vision delay-versus-intensity relationship involves more than just 3 msec throughput receptor characteristics. Lateral interactions over the entire retinal field are centrally important.

Distribution of Excitation and Inhibition in Receptive Fields of Lateral Geniculate Neurones

It has become apparent that the composition of receptive fields of cells in the visual system vary considerably with the species studied, the level in the visual system examined and the stimulus parameters used In spite of this variability, one characteristic form of receptive field has frequently been found at low levels in the visual system It is usually described as roughly circular in shape and is made up of concentric zones which have the same spectral sensitivity The important features of a unit with such a receptive field are that light stimulation in the centre of the field leads to either an increase or decrease in the cell's rate of discharge, while stimulation in the surround leads to a rate change in the opposite direction If both of these regions are stimulated together, the resultant response is a combination of the separate responses of the regions[1]. Thus it appears that at some peripheral point there is a combination of inputs so that the response of the cell indexes the amount of activation received by an excitatory system minus the amount of activation received by an inhibitory system

Two general models have been proposed to show how spatially distributed excitatory and inhibitory effects might be combined to produce the characteristics of the receptive fields described here The basic difference between these two schemes concerns the distribution of the surround mechanism, some assume[2-4] that the centre and surround mechanisms are spatially co-extensive, while others have suggested that there is a spatial discreteness for the centre and surround mechanisms with some overlap at the borders between the two[5] It has been specifically suggested that not only are the centre and surround mechanisms co-extensive, but that the surround mechanism has maximal sensitivity at the same point as the centre mechanism, so that it is chiefly the rate of fall-off in sensitivity that differentiates the two mechanisms The experiment reported here was designed to determine which of these two possibilities better describes the input to cells in the lateral geniculate nucleus of the squirrel monkey (*Saimiri sciureus*)

The activity of single cells in the lateral geniculate nucleus of lightly anaesthetized squirrel monkeys was recorded using micropipette electrodes and conventional recording methods, permanent records of cell activity and stimulus sequences were obtained for later analysis Receptive fields were analysed by presenting various light stimuli on a translucent tangent screen 1 5 m from the monkey Two types of stimulation were used narrow-band spectral stimuli were obtained from a grating monochromator behind the screen, and geometric forms (annuli, spots and so on) were projected on to the front of the screen using tungsten-filament projectors. In addition, full screen illumination was used to provide photopic adaptation conditions

Receptive fields of cells of the lateral geniculate nucleus were initially mapped using flashed spots of monochromatic light (duration, 1 sec, diameter, 20 min.) This procedure provided information on the spatial extent of the centre and the surround of the receptive field In addition, the spectral sensitivity of these two regions was determined, and only those cells that had the same spectral sensitivity throughout were used in this experiment Such cells are of the class previously studied in conditions of diffuse light stimulation, and are termed non-opponent or broad-band[6].

After this initial mapping, responses were obtained by presenting a 20 min spot, centred as accurately as possible in the middle of the centre region of the field Next an annulus was projected onto the screen and positioned so that its centre covered the centre of the receptive field (an area with a diameter of approximately 0 5°–1 2° for such cells) Sufficient time was allowed for the visual system to adapt to the various annular luminance levels, and responses to the centred spot were recorded for each such level In this way, responses were obtained for an annular luminance level equal to the background luminance and for several other levels up to as much as 2 5 $\log_{10}$ units higher

The two models of receptive field organization predict different results from this procedure If the surround and centre mechanisms are spatially discrete, the response to the centred spot should become no greater when annular adaptation is added On the other hand, if the centre and surround mechanisms are spatially co-extensive, adaptation to the surround at some levels might be expected to lead to an enhancement of the response to the centred spot because there should be a range of luminance levels that would affect the surround mechanism but have little effect on the centre mechanism Any adaptation of the centre mechanism, either in the surround from annular stimulation or because of light scatter back into the centre, could only lead to an attenuation of the response to centre stimulation

All cells tested gave a qualitatively similar outcome The results from six such cells are shown in Fig. 1, where the mean response of each cell to centre stimulation is plotted as a function of the annular luminance level and relative to the response without annular adaptation As can be seen, there is a range of luminance levels where the centre response is markedly enhanced over that obtained in the absence of annular adaptation Two points should be noted First, the enhancement effect typically occurs for annular adaptation levels only slightly

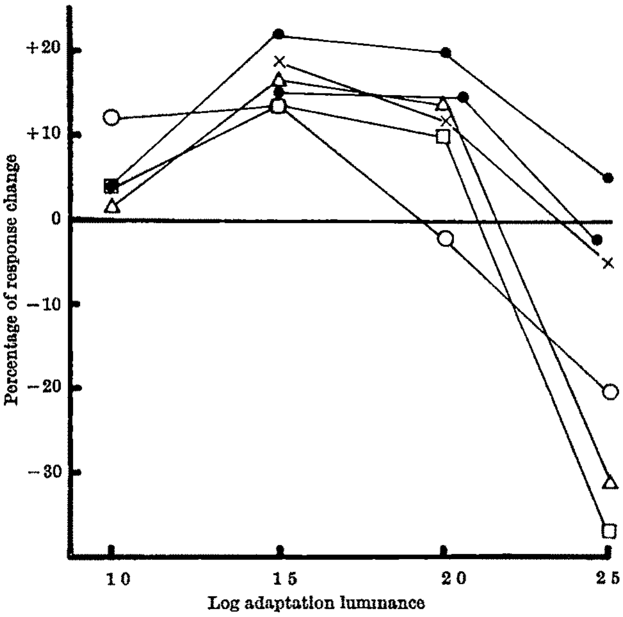

Fig 1 Change in response to centre stimulation for six lateral geniculate nucleus cells as a function of annular adaptation level Response change was calculated from a baseline condition consisting of no annular adaptation

above the background level. At some point above that the response to centre stimulation begins to decline, presumably because at those levels the annular light is also affecting the centre mechanism. Second, although there is variability from cell to cell in the intensity of annular adaptation necessary to produce enhancement, the magnitude of the maximum enhancement effect is roughly the same across cells. The latter feature would seem to indicate that the difference in sensitivity of the centre and the surround mechanisms in the surround is similar from cell to cell. That conclusion, however, seems unlikely in view of the fact that the balance between the centre and the surround of these cells seems to vary rather widely.

The results of this experiment suggest that the centre and surround mechanisms for these lateral geniculate nucleus cells must be to a large extent spatially co-extensive. It should be emphasized that the situation for lateral geniculate nucleus cells possessing spectrally selective receptive fields may be different from the cells examined here, although there is evidence to support the notion that some such cells may also have spatially co-extensive regions[5,7,8]. Finally, there is also the distinct possibility that even cells with the same sorts of receptive fields may be differently constructed in different animals; it has, for example, been reported that for lateral geniculate nucleus cells of this type in another monkey genus, *Macaca*, a centre stimulus is not made more effective by projecting a steady annulus on to the surround[5].

Selection for the Absence of Scutellar Bristles

IN stocks of *Drosophila melanogaster* with a variable number of scutellar bristles, directional selection can increase the number of such bristles[1-3]. Directional selection for the removal of scutellar bristles, however, is rarely successful in the absence of either a sex linked mutant scute allele (*sc*) or a major mutant which similarly reduces the scutellar bristle number to less than four[1,2].

The base population for this experiment, *Vg*6, was homozygous for the recessive mutant vestigial wings (*vg*). This stock had been successfully selected for high sternopleural chaeta number for ninety-six generations[4] and subsequently maintained in mass culture for 6 yr.

Scutellar bristle number assays of *Vg*6 at 25° C showed that 4·8 per cent of females and 0·8 per cent of males had less than four scutellar bristles. Three females and one male each with three bristles were mated together and 125 flies of each sex were taken at random from the resulting progeny and assayed for scutellar bristle number. The female and male flies with the lowest number of scutellar bristles, regardless of the position of the missing bristles, were chosen as the two parents for the next generation. This selection and assay regime was repeated each fortnightly generation. Four single pair insurance cultures were also set up each generation from the flies with the next lowest bristle numbers to insure against the possibility that the best pair should fail to breed. All cultures and assays were made at 25° C.

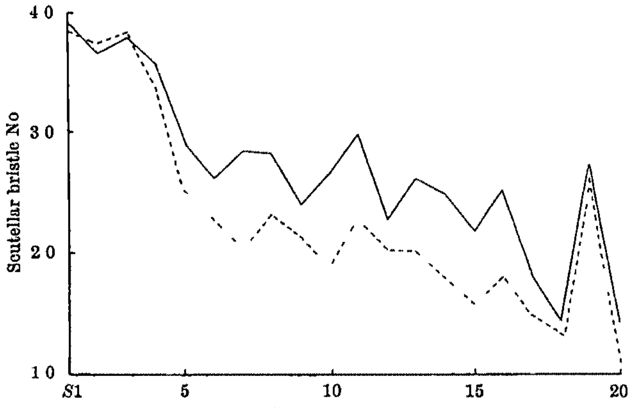

Fig. 1. Response to selection for low scutellar bristle number. ——, Females; - - - -, males.

The results (Fig. 1) show that selection was very effective in reducing the mean scutellar bristle number of both females and males from the four bristles characteristic of the base population. Male flies without any scutellar bristles appeared after only five generations of selection, and from *S*8 onwards neither of the two flies selected for the primary culture had any scutellar bristles.

It is interesting that even after this period, when the selection intensity was inevitably zero, the mean scutellar bristle number of the line continued to fall. The regression of mean scutellar bristle number on generations from *S*8 to *S*20 is negative and significantly different from 0 ($0·05 > P > 0·02$). It seems likely that for these thirteen generations natural selection increased the relative viability of low scutellar bristle number flies. Thus the proportion of flies with a low number of scutellar bristles among the progeny of selected parents increased and the mean bristle number of the line fell.

Each generation the number of bristles missing from the two anterior and the two posterior sites were separately scored. During the early generations of selection only anterior bristles were missing and in the whole experiment the proportion of missing posterior bristles never rose above 38 per cent (Fig. 2).

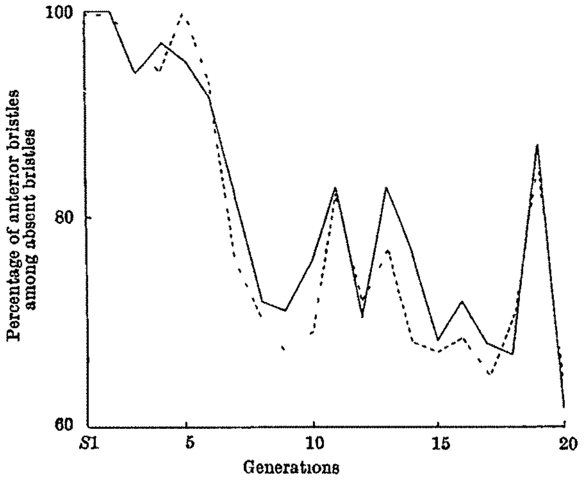

Fig. 2. The proportion of missing bristles at anterior sites in the selection line. ——, Females; - - - -, males.

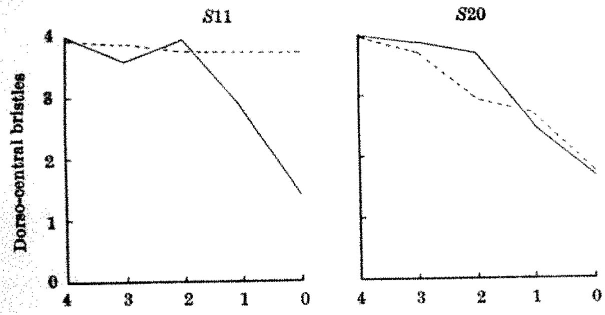

Fig. 3. The relationship between the number of scutellar bristles and the number of dorso-central bristles at generations S11 and S20. ——, Females; – – – –, males.

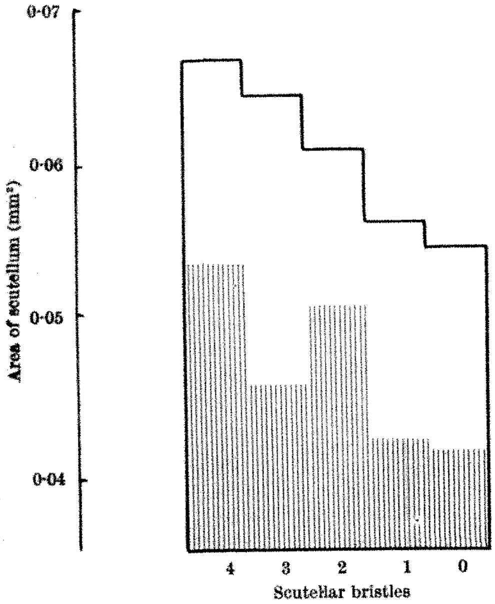

Fig. 4. The area of the scutellum in female flies of different scutellar bristle number phenotypes; shaded area, males.

This apparent gradient in the removal of scutellar bristles was reflected in the chaetaxy of the dorsal surface of the thorax. At generations *S*11 and *S*20 ten flies of each sex and scutellar bristle number phenotype were assayed for the number of dorso-central bristles on the thorax. These assays showed that selection for low scutellar bristle number had a correlated response in the dorso-central bristles which were reduced in number from the four bristles invariably present. Dorso-central bristle number was closely related to scutellar bristle number in females but less closely in males at *S*10. By *S*20 the correlation was similar in both females and males (Fig. 3). It was significant that 68 per cent of the missing dorso-central bristles were anterior in position.

The removal of scutellar and dorso-central bristles was associated with changes in the size of the flies. Flies with no scutellar bristles had a smaller mean scutellum size than flies with four bristles (Fig. 4 and Table 1). There were no corresponding changes, however, in the area of the thorax in the five scutellar bristle number phenotypes.

		(Males hemizygous for a *Vg X* chromosome) Number of *Vg*6 third chromosomes	
		1	2
Number of *Vg*6 second chromosomes	1	4·0	4·0
	2	3·5	2·6

Each epidermal cell in *Drosophila melanogaster* produces a single cell hair (Fig. 5) so that estimates of epidermal cell number can be made by counting the cell hairs in a defined area of the scutellum. The analysis of variance of cell hair assays (Table 2) shows that the only significant degree of freedom is associated with the difference in cell number between females and males. Thus the change in area of the scutellum resulted from a decrease in cell number rather than a decrease in cell size.

Crosses between female flies from the selected line and males hemizygous for sc^1 did not produce any flies with less than four scutellar bristles. Clearly the selection response was caused by factors other than mutant scute alleles which might have occurred and been selected for in the line. Whole chromosome analyses based on male flies from the F_2 of a cross between flies from the line and a standard stock homozygous for the recessive mutants *y*, *bw* and *st* (*X*, second and third chromosome markers respectively) confirm this finding (Table 3). None of the chromosomes derived from *Vg*6 had appreciable individual effects on scutellar bristle number relative to *y*, *bw*, *st*, when heterozygous or homozygous. Male flies heterozygous for the *Vg*6 third chromosome and homozygous for the *Vg*6 second chromosome, however, had a mean scutellar bristle number of 3·6 bristles/fly (Table 3). When the *Vg*6 third chromosome was also homozygous the mean was reduced to 2·7. Substitutions of *X* chromosomes from *Vg*6 did not have a significant effect on mean scutellar bristle number in males.

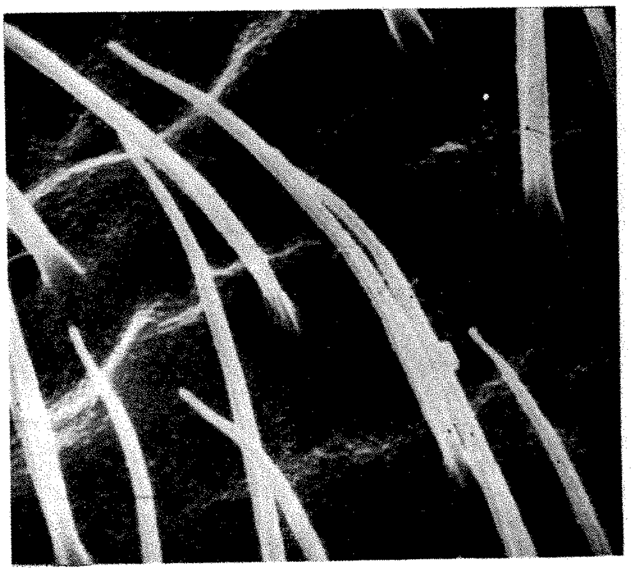

Fig. 5. Epidermal cell hairs on the scutellum (× *c*. 5,360).

These data confirm that by itself the mutant *vg* has little effect on scutellar bristle number in the line although some *vg* alleles do alter the orientation of the scutellar bristles. Nevertheless, the *vg* mutants affect the development of part of the same pair of dorsal mesothoracic imaginal disks that give rise to the dorso-lateral regions of the thorax and the scutellum. Thus the dorso-central bristles and the scutellar bristles derive from a common developmental pathway. As the scutellum was reduced in size but not the thorax, the data emphasize that fly size genes do not necessarily have general effects (compare with ref. 5).

Rendel[3] has shown that canalization of the number of scutellar bristles at four can be changed by the presence of mutant scute alleles. It may be that the mutant *vg* has a similar effect in the present line, for one of the located effective factors is closely linked to the *vg* locus. It is possible, however, that the long history of directional selection for high sternopleural chaeta number in *Vg6* has reduced the canalization of the scutellar phenotype to make the line responsive to directional selection for scutellar bristle number.

In view of the positive correlation between cell number and scutellar number at the end of the selection experiment, we can question whether the changes in canalization, revealed in this experiment, are in any direct way to be regarded as involving changes of the canalization system of scutellar bristle number and pattern. Rather, it seems that the factors determining the pre-pattern[6] of bristle number may have remained constant, but changes of cell number may have "removed" the possibility that the constant bristle pre-pattern be revealed, so that the canalization of scutellum shape and cell number may be the variable that has been manipulated.

I thank Professor J. M. Thoday and Dr P. Lawrence for helpful comments and G. Hudson for assistance. The Cambridge Instrument Co., Ltd., provided the facility of the 'Sterescan' microscope to prepare Fig. 5.

Response of Neurones in the Motor Cortex during Performance of a Simple Repetitive Arm Movement

ANALYSIS of the firing pattern of single cells in the brains of unanaesthetized animals promises to be a useful approach towards understanding brain mechanisms involved in the control of movement. Evarts[1], studying reaction time in monkeys, observed that the firing rate of some pyramidal-tract neurones changes before the electromyographic potential associated with the behavioural response. Evarts's study provided valuable data on the response latency of pyramidal tract cell discharge before a conditioned arm movement. The reaction time task with non-human subjects has the disadvantage that protracted training is necessary to establish fast and stable responses[2], and relatively few behavioural responses are available each day for analysis in relation to unit activity.

We described earlier a technique for concurrent recording of physiological and behavioural data on a two-channel magnetic tape in which the tape recorder was modified so that it could be played backwards[2]. We used a backward summing technique as part of an analysis of muscle potentials occurring just before the behavioural response in a reaction time task. Here we describe an extension of the backward summing technique that shows changes in firing rate of units in the motor cortex of a monkey before and after the animal presses a lever.

A macaque monkey (*Macaca mulatta*) was kept in a primate restraining chair. The animal was first trained to depress a telegraph key to deliver a small food pellet. When the lever pressing response had been well established further responses were reinforced after a variable interval of time (with a mean of 32 seconds) had elapsed since the previous reinforcement (VI 32 schedule). After 2 weeks of training the animal was responding at a rate of about 1,000 responses/h throughout a 3 h daily session. When performance was stable, a stainless steel adaptor was implanted in the skull under general anaesthesia for later coupling with a microelectrode drive unit. The adaptor was positioned over the hand and arm area of the precentral cortex contralateral to the hand used in the training. The dura was left intact and was protected by a silastic rubber plug inside the steel adaptor. Tungsten electrodes etched in the manner described by Hubel[3] were insulated by repeatedly dipping them tip down in thickened Isonel 31 (Schenectady Chemicals, Inc., Schenectady, NY) and baking them tip down between each immersion. Six coats of 'Isonel' applied by this technique covered the electrode up to 10–15μ from its tip, and provided firm insulation which withstood repeated penetration of the dura.

During each recording session the monkey's head was loosely restrained to prevent gross movements. A remotely controlled hydraulic micromanipulator rigidly attached to the steel bone adaptor advanced the tungsten electrode through the rubber plug and dura into the brain. The electrode carrier was so arranged that the angle of penetration could be varied, permitting us to sample neurones within a circle of about 2·5 mm radius using the same skull mounted adaptor. Electrode penetrations were carried out daily while the animal was actively bar pressing. It was difficult to determine when the electrode actually entered the cortex, so the micromanipulator reading that corresponded to the first clearly identifiable unit activity was noted. Cells encountered deeper in the cortex were referenced to this first identifiable unit measure in order to provide a rough measure of each unit's relative depth. When a cell was sufficiently isolated, unit activity was recorded on one channel of a stereo tape recorder while the bar presses were recorded concurrently on the second channel. Data have been gathered on twenty-five well isolated units obtained in seven electrode penetrations. The spikes recorded were subsequently coded onto paper tape through a Schmitt Trigger circuit, and the pattern of cell activity was analysed by computing average firing rates in 20 msec class intervals from 500 msec before the bar press to 500 msec after the bar press. Cell firing prior to the bar press was analysed by playing the tape backwards and using the bar press time mark to initiate the computer's 500 msec analysis period. Cell firing after the bar press was similarly analysed by playing the tape forward. The number of behavioural responses used to establish the average firing rates varied from 38 to 200 depending on how long the cell was held.

Fourteen of the twenty-five cells from which we recorded changed their firing pattern before the behavioural response. This change took one of two forms: some cells that had a relatively low resting rate of discharge were phasically activated, while others that were tonically active transiently lowered their firing rate prior to the response. Representative single cell records and their averaged firing rates are shown in Fig. 1.

Although our measure of depth in the cortex was crude, it was sufficient to show that nearly all cells

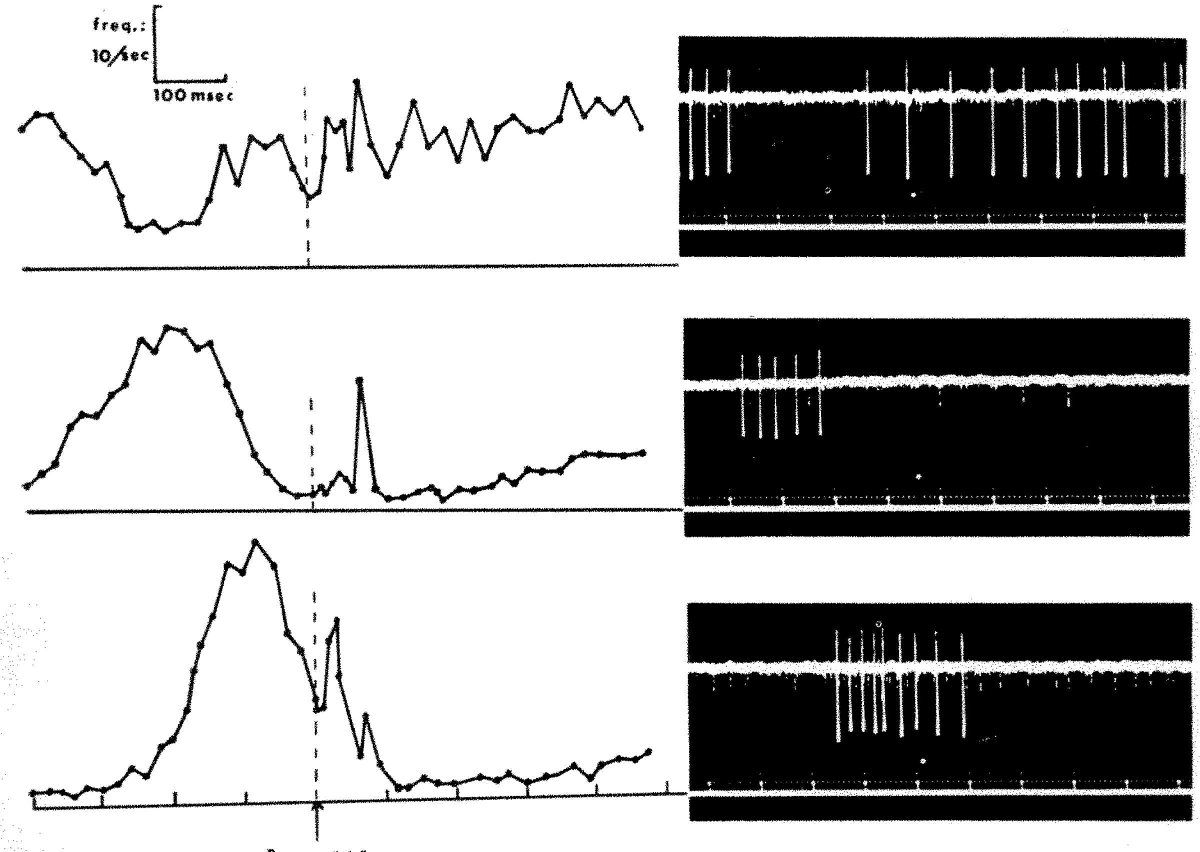

Fig. 1. Average firing rates and representative single cell recordings of three cells recorded in the same penetration. The oscilloscope photographs were made from taped records. The negative portions (downwards) of the units have been brightened by applying the negative portion of the input signal to the oscilloscope's intensity-modulation system. The bright dot above each time line indicates the occurrence of the bar press. Time marks are 10 and 100 msec. These three cells, recorded in the deeper layers of the cortex, showed consistent modification of their firing pattern before the response. Two cells isolated in the same penetration at more superficial levels had no apparent correlation of firing pattern with the response. The sharp post-response deflexion seen in the middle graph consists of a single discharge at a fixed interval after the response. Three cells of the sample had this characteristic.

consistently modified by the response were relatively deep in the cortex. The first few cells in any penetration had very low spontaneous rates, and became intermittently active in bursts with no apparent correlation to the monkey's bar pressing.

Although we do not know whether the deep cells were pyramidal tract neurones or not, the general form of the response patterns confirms the "tonic" and "phasic" distinction made for pyramidal tract cells by Evarts[4]. Moreover, their depth in the cortex suggests that the recorded cells lie in the layers of the precentral cortex which give rise to cortical efferents. Even the most strongly modulated phasic cells did not fire faster than 50/sec. This supports Evarts[5] suggestion that precentral cells in the awake animal may be subject to a frequency-limiting mechanism.

Our technique of recording and analysis offers some advantages for study of brain mechanisms in movement. The method may be readily adapted to other sites in the brain or to other movements.

MICROBIOLOGY

Chemotaxonomic Studies of some Gram Negative Bacteria by means of Pyrolysis–Gas–Liquid Chromatography

THERE has recently been a great need in medical microbiology for more rapid and objective methods of differentiating pathogenic micro-organisms. Earlier work[1,2] indicated that sub-species differences among diverse taxa could be detected by means of gas-liquid chromatography of their whole cell pyrolysis products. The present study confirms these results and shows that the distribution of pyrolytic products is a constant factor and is directly related to the chemical structure of the micro-organism.

The biochemical and serological procedures employed in the characterization of the cultures used were the same as those described by Ewing[3] and Edwards and Ewing[4], which were similar to those given by Kauffmann[5,6] and Ørskov[7]. Smooth cultures of *Escherichia coli* and *Shigella* serotypes as well as representative examples of other genera were inoculated into trypticase soy broth. The tubes were incubated with agitation for 6 h at 37° C in a water bath. Growth from these cultures was used to inoculate large (200 × 35 mm) plates, each of which contained either 350 ml. of freshly prepared meat infusion agar medium or a simple peptone yeast extract medium. A sample (1·2 ml.) of the broth cultures was spread on the surface of each plate. After incubation for 21 h at 37° C, the growth from each plate was collected in 10 ml. of distilled water containing 0·5 per cent formalin, centrifuged (10,000*g* for 15 min), resuspended in the same diluent and recentrifuged. The cells were washed three times in this way. The heavy suspensions of washed cells were lyophilized and stored at room temperature in screw-capped bottles.

Details of the pyrolysis–gas–liquid chromatography (PGLC) procedure and equipment used have been described elsewhere[2]. In brief, the method consists of subjecting a pellet of dry bacteria (100–275 ± 1·0 μg) to a rigidly controlled pyrolysis. A gas chromatographic system directly connected to the pyrolyser separates the thermal fragmentation products. A pyrogram or graph showing the pattern of these products is traced on a strip chart recorder.

One question which arises is whether the criteria used for distinguishing organisms are in fact related to differences in their chemical structure and not related to variations inherent in the technique. Instrument variation is not a significant factor, as numerous tests have shown. In a typical example, a single sample of *E. coli* 0105 was analysed five times in succession. Weights of samples varied from 143 to 200 μg. Individual peaks had retention times ranging in mean absolute deviation from 1 to 4 sec. Amplitudes of individual peaks (concentration) indicated good precision as well. The following is more important, however, from the standpoint of diagnosis: pyrograms from a variety of micro-organisms (2,400 analyses) show that certain areas or peaks of the profile are characteristic. These characteristic peaks, used to distinguish organisms, are constant and reliable. Such peaks seem to be unaffected by a number of factors, and these will be discussed.

The investigation involved sixteen 2 year old cultures analysed previously and thirty-three fresh cultures. The fresh cultures were coded and their antigenic schema was not available to the analyst before all pyrograms were completed. Every sample was analysed at least twice on each gas–liquid chromatography column. Although columns were prepared in an identical way, pyrograms of a single organism, analysed on different columns, may show some modification in pattern. In all, 316 analyses were recorded.

When the analyses were completed, pyrograms of the coded samples were sorted into five groups. These divisions were based on the ratios of two characteristic peaks: peak 8 (R_T, 900 sec) and a double peak, 9*a* and 9*b* (R_T, 1,010 sec). Group 1 consisted of nine profiles with peak 9 taller than peak 8. All of these were later found to be 055 serotypes. Group 2 comprised four pyrograms with peak 9, in this case, shorter than peak 8; group 3 was made up of five pyrograms with peak 9 equal to peak 8. Groups 2 and 3 proved to be *E. coli* 0111 serotypes. Group 4 included fifteen samples in which peak 8 was missing altogether. This group was further divided into those pyrograms with (1) 9*a* taller than 9*b*, and (2) 9*a* equal to 9*b*. The latter were found to belong to *E. coli* 0 group 105 (formerly designated 0115) (ref. 1) and *Shigella boydii* 10. In addition, some groups contained pyrograms which were identical in every respect (obviously duplicates). Conversely, some pyrograms within a group had small differences. At this stage, it could not be established whether these small differences were consistent, thus characteristic ones, so no further subdivisions were made.

When the identity of the samples was disclosed, nine serotypes had, in fact, been represented in the five groups. Now, however, additional subdivisions, based on small differences in the profiles already recorded, could readily be made. The small differences proved to be characteristic of the serotypes in question.

Typical pyrograms of each group are shown in Fig. 1. On both chromatography columns, pyrograms fall into two principal patterns: on column 1, those with a peak at position 8 were *E. coli* 0 groups, 111 and 55. All others lacked this peak. The same divisions appeared in analyses performed on column 2. Those profiles having peak 8 on column 1, however, now had a double peak 6 on column 2; those lacking peak 8 on column 1 now had a single peak 6. On both columns these characteristic peaks always had a retention time close to 18 min. *E. coli* 0 group 1, unlike all the others, showed a prominent peak between 6 and 7. These findings indicate a relationship between organisms within each of the two principal groups. As far as is known, such a relationship has not been established by serological or other methods currently used.

In this investigation, experiments were designed to achieve several objectives, as follows. In a series of experiments on coded samples, one test was designed to measure how well closely allied organisms could be distinguished. Two samples of *E. coli*, 0111*a*, 0111*b* : *B*4 : *H*12 and 0111*a*, 0111*c* : *B*4 : *H*4, which differ only in the

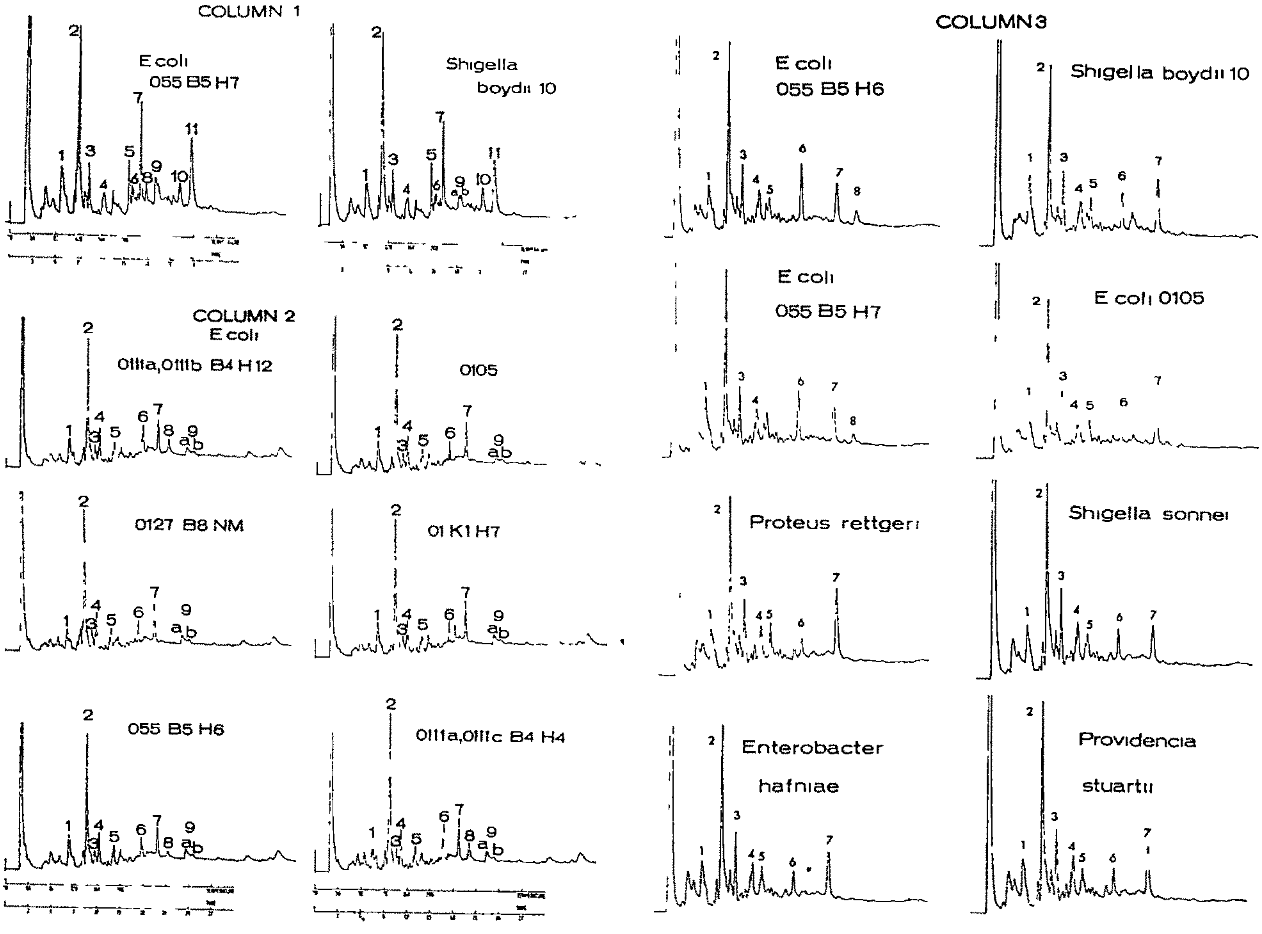

Fig. 1

somatic antigen sub-type and in the kind of flagellar antigen, were analysed Pyrograms showed consistent differences in ratios of peak heights of peaks 9*a* and 9*b* (see Table 1, gas–liquid chromatography column 2)

In another example (Fig 1) are shown pyrograms of *E coli* 0105 and *Shigella boydii* 10 Because these organisms share O and K antigens, serological differentiation is very difficult On the other hand, in their respective pyrograms, recognizable differences in pattern are shown between peaks 6 and 7

In addition, *Shigella sonnei*, which has no serological relationship to the other two, differs only between peaks 6 and 7. *A priori*, if pyrolysis profiles are indeed a reflexion of the original antigenic structure of the micro-organism, a much greater difference should be expected in a comparison of *S sonnei* and *E coli* 0105 than with *S boydii* 10 and *E coli* 0105 Such differences, however, are not revealed (Fig 1), it is therefore concluded that pyrograms do not always show a direct association with serological findings and therefore they must be showing other differences

Serological data are lacking for *Enterobacter hafniae* Together with *Providencia stuartii*, they give similar pyrograms (Fig 1; slight differences at peaks 4 and 5) These are, in turn, quite different from the profiles obtained from all cultures of *E coli* which have been studied

In a second test, two cultures of *E coli* 0111*a*, 0111*b* *B*4 *H*12, each isolated from different sources (human), were analysed Their PGLC profiles were superimposable

In another example, two organisms which were of the same serotypes, 055 B5 *H*6, but derived from different human sources, again yielded pyrolysis profiles which were identical when superimposed In addition, profiles from a variety of non-enteric pathogens, obtained in the same conditions, also have given superimposable pyrograms

A third set of tests concerned the following effects changing the culture media (blood agar base to peptone yeast extract), inoculating and collecting cells at different times (during 3 weeks), varying the storage period of lyophilized cells (days, up to 2 yr) In each instance, pyrolysis profiles, when judged by their characteristic peaks (peaks which impart uniqueness), remained unchanged by these modifications

A fourth test was designed to see whether the method could permit differentiation between even more closely related organisms Two *E coli* cultures of known serotype, 055 *B*5 *H*6 and 055 *B*5 *H*7, were chosen for comparison As far as is known, they differ only in their flagellar, H, antigens The H antigens are thought to be composed almost entirely of a protein, flagellin, which represents up to 2 per cent of the dry weight of the cell[8]. The analytical results, illustrated in Fig 1, show that a small peak, 2*a*, which follows the notched peak 2, appears below the notch on H6; above the notch on H7 Peaks 4 and 5 also show different relationships These small differences appeared consistently in every pyrogram (twenty-four) of the two samples

The fine distinction between these organisms, based on what seems to be a minute amount of dissimilar protein, raises the interesting point as to what specific chemical structures or combinations are contributing to the total pyrolysis pattern This question, as well as investigations on cell wall antigen structures and electronic data processing, is under study

BIOLOGY

Natural Selection by Glow-worms in a Population of *Cepaea nemoralis*

There are very dense populations of *Cepaea nemoralis*, the polymorphic land snail, on the sand dunes of the nature reserve of Newborough Warren in Anglesey, Wales They occur sporadically, chiefly in areas of dune colonized by *Salix repens*, and contain individuals of the usual phenotypes—yellow or pink and banded or unbanded Some populations also contain considerable numbers of the brown phenotype While sampling one of these populations with Dr K Isarankura, glow-worms were occasionally to be found feeding on the snails During a survey of the area at night, about thirty-three glow-worms were seen in an area of 10 m square, the actual population no doubt being denser than this Glow-worms may therefore well be an important predator of *Cepaea* and if they preferred one phenotype to another they might have a strong selective effect. An experiment was set up to test for any preferences the glow-worms may have for particular phenotypes A glow-worm was put in a bowl with a choice of two snails to eat The choices were either of brown and banded yellow or of unbanded and banded yellow The experiments were carried out in the autumn of 1965 and 1967 Table 1 gives the data when the choice was of brown and banded yellow and Table 2 the data for unbanded and banded yellow The results show that both brown and unbanded yellow are preferred to banded yellow but that there is heterogeneity in the results for unbanded and banded yellow If the data in Tables 1 and 2 are combined, the overall preference for brown or unbanded yellow becomes very significant ($0{\cdot}005 > P > 0\ 001$), the heterogeneity in the combined data is not quite significant If there is significant variation in the results of the experiments, it could be caused by a varying preference in different glow-worms The data for 1967 were obtained by using some of the glow-worms more than once The sequences of their choices were recorded the data and their analysis are shown in Table 3 There is no evidence for a correlation between successive choices of a glow-worm and no evidence therefore for variation in preference between glow-worms

Bd Y	1	3	4
Totals	8	6	14

Fisher's exact test for both tails of the distribution gives a probability of $P = 0\ 245$ which is without significance

The preference shown by the glow-worms in these experiments may explain a sharp cline in the frequencies of the brown phenotypes The population we studied extends along a small dune for about 150 yd In the area where the glow-worms are found at the northern end of the population browns occur with a frequency of about 10 per cent But at the extreme southern end of the population about 40 per cent are brown, the frequency of brown decreasing sharply over about 80 yd The glow-worms are not to be seen where the browns are common Because there is almost a 2 to 1 preference for brown by the glow-worms it is tempting to suggest that the cline of decreasing brown is caused by increasing glow-worm predation It is therefore possible that the glow-worm predation may be a factor affecting the "area effects" that were extensively studied by Cain and Currey[1] They showed that in certain areas the frequencies of the different phenotypes in populations of *Cepaea* were not correlated with the background of the environment from which the populations were sampled Visual selection of the phenotypes by birds was presumably not the factor determining the frequencies Glow-worms might, however, be a selective predator Cain and Currey found populations with high frequencies of browns and noted that they were usually in areas where cold air might be expected to accumulate on clear nights suggesting that brown might be hardier, but it would be interesting to know if glow-worms were present or not

Production of Auxin by Detached Leaves

In senescent leaves proteins are hydrolysed to amino-acids and peptides[1], which might be expected to release protein-bound auxin and also to provide considerable amounts of tryptophan which can be converted by many plant tissues to the auxin indolyl-3-acetic acid (IAA). We have therefore investigated the concentrations of auxin in senescent leaves.

Mature trifoliate leaves from plants of *Phaseolus vulgaris* and leaves from young plants (2–3 weeks old) of *Avena sativa* were detached and placed with their petioles or bases in distilled water in the dark at 25° C. In these conditions, the leaves become senescent and turn yellow. Samples were taken at various times (at intervals of 1 or 2 days), weighed and stored in the deep freeze until they were extracted with peroxide-free ether for 3 h at 0° C. The ether extract was partitioned and the acidic fraction was run on paper chromatograms with isopropanol : ammonia : water (8 : 2 : 1 v/v). The zone corresponding to IAA was eluted and the auxin was estimated using an *Avena* coleoptile straight growth bioassay. The amounts of auxin extracted from the leaves at various times are shown in Figs. 1 and 2.

It can be seen that in both cases there is a large increase in the amount of auxin present over a period of 6 days. The amounts measured represent the resultant of auxin production and auxin destruction: in the case of *Avena*, after about the fourth day the rate of destruction exceeds the rate of production. The fall in total auxin was observed in each of six experiments. Libbert *et al.*[2] maintain that most of the IAA which can be extracted from plants is formed by epiphytic bacteria, but because plants do not normally grow in sterile conditions this alleged bacterial production of IAA is likely to be very significant physiologically. Thus although the experiments reported here were not performed in sterile conditions, the results are relevant whether or not the auxin is formed in part by epiphytic bacteria.

Young expanding leaves are an important source of auxin in the plant and concentrations of auxin in mature leaves are low[3-5]. The concentrations of auxin in attached senescent leaves, however, have received little attention, and such measurements as have been made have been based on relatively infrequent sampling (usually at intervals of about 10 days). A peak of auxin production during leaf senescence could therefore have been missed. The level of auxin in leaves and petioles is involved in the control of abscission[6] so the production of auxin by senescent leaves, if it is a general phenomenon, may be an important factor which so far has been overlooked.

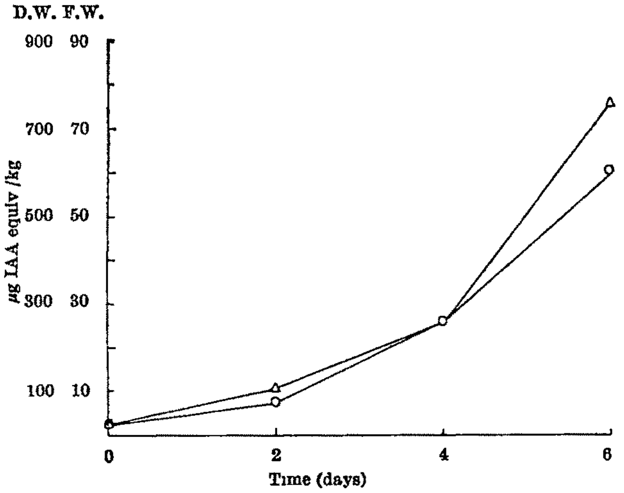

Fig 1. Auxin levels in detached *Phaseolus vulgaris* leaves. Expressed on dry weight (D W, ○) and fresh weight (F W, △) basis.

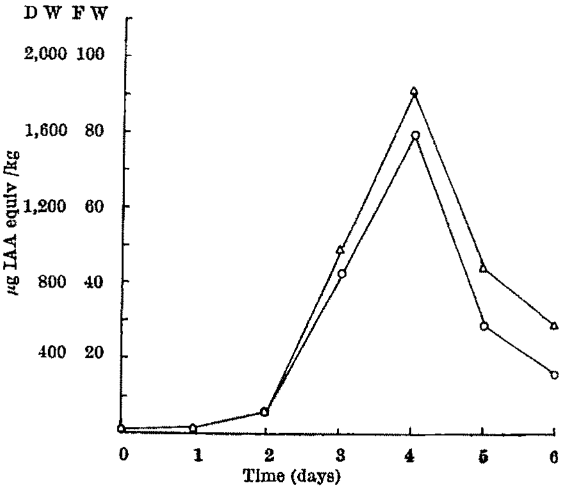

Fig 2. Auxin levels in detached *Avena* leaves. Expressed on dry weight and fresh weight basis as in Fig 1.

We have suggested elsewhere[7] that dying cells are a principal source of auxin in the plant. Because cell death is frequent in normal growth, differentiation and development of the plant, the production of auxin by senescent, dying leaves may be only one example of a much more general process.

GENERAL

"Least-squares" Estimation of Distribution Mixtures

The statistical estimation of the unknown fractions Π_i ($i = 1, \ldots k$), and, when unknown, further parameters $\theta_j (j = 1, \ldots m)$, in a mixed population which is denoted by its cumulative distribution (taken to be univariate)

$$F(x) = \sum_{i=1}^{k} \Pi_i F_i(x)$$

is, in general, cumbersome. It therefore seems worth noting the convenience and comparative efficiency, at least in relation to the estimation of the Π_i, of estimators of "least-squares" type, defined by the minimization of the integral

$$\int (\mathrm{d}F_s - \mathrm{d}F)^2/\mathrm{d}G$$

where $F_s(x)$ denotes the cumulative distribution of the empirical sample (from, for example, n independent observations), and $G(x)$ is a suitable increasing function of x. Taking for simplicity the case $m = 0$, the estimators of the Π_i are automatically unbiased with exact variances readily calculable, and with asymptotic normality. For example, if $k = 2$, we have an estimate p_1 for Π_1,

$$p_1 = \frac{\int (\mathrm{d}F_s - \mathrm{d}F_2)H}{\int (\mathrm{d}F_1 - \mathrm{d}F_2)H}$$

for example, where $H=(\mathrm{d}F_1-\mathrm{d}F_2)/\mathrm{d}G$, with the expected value $E(p_1)=\Pi_1$, and variance

$$\sigma^2(p_1) = \frac{\int H^2\mathrm{d}F - (\int H\mathrm{d}F)^2}{n[\int(\mathrm{d}F_1 - \mathrm{d}F_2)H]^2}$$

A considerable choice of H is possible   Thus, considering for definiteness the density case, we define the unweighted least-squares estimator of Π_1 by the choice $\mathrm{d}G=dx$, $H=f_1-f_2$ We should, however, expect weighted estimators to be better   In fact, because the variance of $\mathrm{d}F_s$ is fdx/n, we should try to choose $\mathrm{d}G=fdx$, the term $\int H\mathrm{d}F$ in the expression for $\sigma^2(p_1)$, arising from the covariance of $\mathrm{d}F_s(x)$ and $\mathrm{d}F_s(y)$, then vanishes, and $\sigma^2(p_1)$ becomes identical with the reciprocal of the information function $I(\Pi_1)$ If we take $\mathrm{d}G=\Pi_0\mathrm{d}F_1+(1-\Pi_0)\mathrm{d}F_2$, then this weighting will be most efficient when Π_0 is close to Π_1 Thus if we suspect Π_1 to be near 1, $\frac{1}{2}$ or 0, suitable choices for Π_0 would be 1, $\frac{1}{2}$ or 0, respectively. An alternative to $\frac{1}{2}(\mathrm{d}F_1+\mathrm{d}F_2)$ is the geometric mean of $\mathrm{d}F_1$ and $\mathrm{d}F_2$, and another is $\max(\mathrm{d}F_1, \mathrm{d}F_2)$. The geometric mean has some convenience over the arithmetic mean in theoretical investigations of efficiency (for example, for f_1 and f_2 normal), but the latter (or alternatively $\max(\mathrm{d}F_1, \mathrm{d}F_2)$) has the advantage of approximating to the maximum likelihood estimator, for any value of Π_1, in both the extreme cases of f_1 and f_2 well separated and of $f_1\rightarrow f_2$ It has been shown by Hill[1] that the information function $I(\Pi_1)$ for Π_1 may be written $n[1-S(\Pi_1)]/(\Pi_1\Pi_2)$, where

$$S(\Pi_1) = \int(f_1f_2/\mathrm{f})\mathrm{d}x$$

If f_1 and f_2 differ by some parameter μ (for example, the mean), and $\Delta\mu=\mu_2-\mu_1$, then also as $f_1\rightarrow f_2$,

$$I(\Pi_1) \sim n(\Delta\mu)^2 I(\mu)$$

where $I(\mu)$ is the information function for μ Thus for the maximum likelihood estimator $\hat{\Pi}_1$ the variance, which is $\Pi_1\Pi_2/n$ for f_1 and f_2 well separated, is $1/[n(\Delta\mu)^2 I(\mu)]$ as $f_1\rightarrow f_2$

In the case of further unknown parameters θ_j the problem is obviously more complex, because of the non-linear dependence of f on θ_j, but linearization of the estimation equations may sometimes be convenient   For example, for two populations with unknown parameters θ_1, θ_2, respectively, we might adopt the standard least-squares procedure of taking provisional values v_1, v_2, say, so that in the "sum of squares" to be minimized we write in the numerator

$$f \sim f_2(v_2) + \Pi_1(f_1(v_1) - f_2(v_2)) + \varphi_1\partial f_1/\partial v_1 + \varphi_2\partial f_2/\partial v_2$$

in the unknowns Π_1, φ_1 and φ_2, where

$$\varphi_1 = \Pi_1(\theta_1 - v_1),\ \varphi_2 = \Pi_2(\theta_2 - v_2)$$

(retaining the provisional values v_1 and v_2 in the weighting-function $\mathrm{d}G$)

Speculations on the Use of Orthonormal Functions in the Study of Morphogenesis

THE recent proposal[1] to analyse shapes of biological objects by means of orthonormal functions opens up some interesting possibilities   In the work cited, a particular set of two-dimensional orthonormal functions synthesized from Walsh[2] functions which take only the values +1 and −1 was used   As is well known, however, there is a vast number of other complete sets of orthonormal functions and, in fact, they could be constructed indefinitely   There are also standard linear methods for transforming from one set of orthonormal functions to another, these procedures can be realized as computer programmes

The Walsh-derived functions are most suitable as an initial set because of their simplicity   Their characteristic chequerboard patterns, however, are not the most natural to use for the analysis of familiar kinds of biological objects, this was indicated by the fact[1] that, for good accuracy, as many as 256 terms might be needed in the expansion for a leaf   It might be possible to construct a different orthonormal set of basic patterns which would be more "leaf-like" in shape, ideally, a development series of leaves would all be adequately described by merely two or three terms, say   What is required then is to devise computer programmes which, for a given series of input shapes, would find the best orthonormal set—using the transformation procedures referred to—best in the sense that fewest terms would be required for adequate description   When this had been achieved, one might hope to discover laws of a general type from the experimental data, for example, by studying the changes of the weights (that is, coefficients in the orthonormal expansion) that occur in development or because of experimentally applied external agents   If this were achieved, the basic patterns would presumably have genuine biological significance

What follows is rather more speculative   It is well known that most of the standard orthonormal functions of mathematical physics (sinusoidal or Bessel, for example) arise naturally in the solution of differential equations with boundary constraints   Thus a given set of orthonormal functions characterizes a given differential equation with its associated boundary conditions   If then an orthonormal set which was particularly adequate in the sense of the previous paragraph was found, this set might well have a special significance and be indicative of some differential equation or, maybe, difference equation or other type of equation, which characterizes in a general way the development of the patterns concerned   It might thus be possible, merely from examining the optimum orthonormal sets generated by the computer programmes, to draw conclusions about or even to derive the fundamental laws—in the form of differential equations or something similar—which govern the development of form.

Another issue, which it may be fruitful to investigate, is the biological meaning, if any, of the maximal weights previously discussed[1]. If one attempted to reconstruct a form from the maximal weights directly, one would fail, because in general the constructed function would have other values than 0 and 1. Nevertheless, this function, because it contains all the information about the degrees of resemblance of the form concerned to the basic pattern forms, should have a significance which might be usable—especially in those cases where the number of basic patterns effectively used is very small, as discussed previously

It would also be useful to generalize the orthonormal expansion method by allowing the form function to have more than two values   For example, a representation of the veins of a leaf might be included with a value of 2 being assigned at locations on a vein   This would provide a three-valued function, but many-valued functions could be used also for other purposes such as giving the distribution of colour as well as shape of an object, when a suitable numerical coding of the colours had been chosen

BOOK REVIEWS

PHYSICS OF HADRONS

Algebraic Theory of Particle Physics

Hadron Dynamics in Terms of Unitary Spin Currents By Yuval Ne'eman (Frontiers in Physics). Pp xvi + 334 (New York and Amsterdam W. A Benjamin, Inc, 1967) $10 cloth, $5 95 paper

The Interactions of Hadrons

By Hartmut Pilkuhn. Pp xi + 375 (Amsterdam North-Holland Publishing Company, 1967) 100*s*

THE past decade has seen three major advances in hadron physics The first was the discovery of parity violation in Weak interactions, with its elegant explanation in terms of the two-component neutrino This implies equal strengths for axial and vector lepton currents and suggests that the axial and vector hadron currents in the Weak interaction would also appear with equal coupling constants if Strong interaction effects could be switched off

The second advance culminated in the discovery of Ω^-, which in turn established that the Strong interactions are approximately invariant with respect to operations of the group $SU(3)$ The symmetry breaking interaction is about one order of magnitude weaker than the dominant Strong interaction, and is still invariant with respect to the subgroup $U(2)_I$ (isotopic spin and hypercharge) $SU(3)$ is an eight parameter group, and so it gives rise to eight currents which in the basic (quark) representation and conventional notation are written

$$J^i_\mu(x) = \bar{\psi}(x)\gamma_\mu \lambda_i \psi(x) \text{ with } i = 1, \quad , 8$$

These are all approximately conserved, and those corresponding to isotopic spin and hypercharge are exactly conserved apart from electromagnetic and Weak interaction effects

The third major line of progress has been the establishment of a number of links between the currents arising from the Strong symmetry and those appearing in the electromagnetic and Weak interaction Lagrangians

(i) The crucial consequence of the (correct) 8-fold-Way version of $SU(3)$ is that the electromagnetic current can be expressed as a linear combination of those $SU(3)$ currents which are related to isotopic spin and hypercharge

(ii) The CVC hypothesis states that the vector hadron currents appearing in the Weak interaction are also the appropriate components of the $SU(3)$ octet of currents The fact that the isotopic spin current is conserved implies that the corresponding vector coupling constant is not renormalized by Strong interaction effects

(iii) The PDDAC hypothesis asserts that the Pion Dominates the Divergence of the Weak interaction Axial-vector Current, in the sense of dispersion relations This means that the divergence of the axial current behaves like the pion field, with a constant of proportionality which depends on the particle masses, the Strong coupling constant and the ratio of the observed axial to vector Weak coupling strengths, G_A/G_V (This is often called PCAC)

(iv) By far the most adventurous of this chain of assumptions is that which asserts that the hadron currents appearing in the Weak interaction satisfy the algebra (or the commutation relations) obtained from the simple form of vector $SU(3)$ currents $J^i_\mu(x)$, and for the axial-vector currents the similar expressions with γ_μ replaced by $\gamma_\mu\gamma_5$ This has led notably to the Adler–Weisberger relation which depends on $SU(2)$ invariance of the Strong interactions and all the properties of the Weak interaction mentioned above It correctly relates the ratio G_A/G_V to pion–nucleon scattering, and appears to confirm this chain of assumptions about the Weak interaction It throws no new light on the symmetry properties of Strong interactions

On the basis of these successes, the problem which has received most attention in recent years is the further elucidation of the hadron spectrum, which can be approached either directly or indirectly through high-energy scattering and its analysis in terms of fixed or Regge poles The problem is to find the relation between the observed hadron masses, their spins and $SU(3)$ multiplet properties A considerable advance appeared to have been made with the proposal of $SU(6)$ which correctly predicts both $SU(3)$ and spin properties of the low-lying mesons and baryons and the ratio of proton to neutron magnetic moment But there appear to be fundamental difficulties with any symmetry which couples internal ($SU(3)$) properties to the external (space–time) properties of parity and spin

To understand the present paradoxical situation, it is instructive to consider a model world with only two spatial dimensions Thus we can visualize the flat-land physics which would be developed by two-dimensional physicists confined to a plane If there were no preferred position or direction in the plane, they would observe invariance of physical laws with respect to displacements and rotations about an axis perpendicular to the plane. Consequently they would find conservation of linear momentum and simultaneously angular momentum in the plane about an axis through the centre of mass. They would find intrinsic spin (in the plane) which in units of h could take on integer or half integer values m; but there would be no reason to expect any multiplet structure relating particles with different m values

Suppose now that it was found experimentally that the particles did in fact group themselves naturally into multiplets of approximately equal mass with m values which were observed to satisfy a relation

$$-j \leqslant m \leqslant j.$$

The physicists would interpret this as some internal symmetry, but to the mathematically minded flat-landers it would immediately suggest three-dimensional rotations $O(3)$ They could perfectly consistently postulate that single particle states were invariant with respect to three-dimensional rotations, since in the rest frame these rotations would not take the particle out of the plane (In a three-dimensional relativistic theory $O(3)$ would be replaced by $SU(6)$ or $U(6) \times U(6)_{\gamma_0}$, and I will continue to indicate in parentheses the corresponding generalizations)

To explain the origins of the $O(3)$ rule, they might assume that relative motion can be neglected in Strong short range interactions and that the remaining spin–spin interactions are invariant with respect to three-dimensional rotations This would be logically consistent, but would predict that spin (not angular momentum) in the physical plane would be conserved It would forbid, for example, the decay of a high-spin object into any two objects of smaller spin That would require orbital angular momentum to give overall conservation ($SL(6,C)$ or $U(6,6) = \widetilde{U}(12)$)

If this were contrary to observation, the two-dimensional physicists might conjecture that "reality" was in fact three-dimensional, invariant with respect to three-dimensional rotations—of which they were observing a two-dimensional section ($IU(6,6)$) To write down momentum-dependent and invariant interactions, it would be necessary to introduce momentum as a 3-vector (not just a 2-vector) and then to impose the condition that, for all physical processes, the momenta lie entirely in the physical plane The extra dimension is not in fact a serious problem The only physical implications of the assumed higher symmetry apply to collinear processes, such as forward scattering or two-body decay, which in their rest frame involve one direction These must now be invariant with respect to rotations about that direction—an axis in the physical plane defining rotations which do not remove the process from the plane If these latter are called W-rotations, we may recover all the physical implications of the wider symmetry by postulating $O(3)$ invariance for single particle states and W-rotation invariance for collinear processes, without ever mentioning three-component momenta $(SU(6)_W)$ The two statements have identical physical content The formulation which refers to extraphysical dimensions is intuitively clearer; the latter sacrifices some intuitive clarity for the advantage of not even referring to unphysical quantities.

There is, however, a serious difficulty with probability, which must still be conserved in the real two-dimensional world. The consequent unitarity of the S-matrix enables one to express the imaginary part of a forward scattering amplitude as a sum over all energetically possible processes. These latter are not in general collinear and thus do not have the extra W-spin symmetry required for the forward amplitude. Consistency between W-spin invariance and unitarity is only possible if the dynamics of the hadrons leads exclusively to forward (or backward) scattering. But since forward scattering is the limit of non-forward the simplest analyticity requirement on the S-matrix excludes non-vanishing forward scattering if scattering through any finite angle is zero

The two-dimensional model accurately illustrates the problems of higher symmetries which combine internal and external transformations A possibility which is not apparent from this simple model is to assume that the particles form infinite unitary multiplets of the non-compact groups which arise when the theory is made relativistic. This is clearly a very drastic approximation and, in fact, leads to further troubles

One can try to avoid the problem by noting that the bottom end of the meson spectrum is just that to be expected from a quark–antiquark pair bound in any simple potential. This model treats an extreme relativistic situation in which about 80 per cent of the original rest mass has disappeared into binding energy as though it were non-relativistic nuclear physics. It fails to explain the baryon states since pairs of quarks must not bind, and three quarks bind in mutual p-states—not natural properties of simple potentials. It purports to replace group theory by specific dynamics, but the dynamical model fails already for one particle states and is quite unbelievable for scattering, where the real difficulties arise It may yet "predict" the correct meson spectrum, but it does not solve the problem.

The two books by Dr Pilkuhn and Dr Ne'eman approach this material with very different intentions, but I cannot enthuse about either of them. Dr Pilkuhn has restricted himself to the well-established parts of the subject, and has written an introductory text suitable for someone starting research in this field He deliberately avoids the use of operator fields, which to my mind is a disservice to the student, for fields provide much the simplest vehicle for discussing both the invariance and the analytic properties of the S-matrix, particularly when antiparticles are involved. They do not depend on weak interactions or a Lagrangian Consequently anti-particles are here introduced almost apologetically and the important CTP theorem is not covered

The book deals with the phenomenology of pion-nucleon and kaon-nucleon scattering, but the Poincaré group is not mentioned and the formalism excludes the introduction of operator currents. As a result, the treatment of Weak interactions is clumsy, and generally the text does not lead naturally into those fields which are now of most active theoretical interest

Dr Ne'eman's book, on the other hand, is aimed at research workers who already have some experience in the field, and sets out to give an up-to-date account of the application of group theory to hadron physics He is thus directly concerned with the material summarized above The book is interesting since the subject matter is extremely interesting, but the treatment is obscured by the author's personal jargon and a partisan approach Thus current algebras are referred to throughout as TOA, Weak becomes "atonous", and internal "endo" with no increase in clarity The $U(6,6)$ theories are introduced with the revealing phrase—"one should perhaps mention the attempt to work with 'redundant components' ". It is not explained that the redundant components referred to are just the four components of Dirac theory which generalize the two component non-relativistic spinors, and are precisely the mechanism whereby one can produce an $SU(6)$ static limit and at the same time preserve all the attractive features of a local causal theory—crossing symmetry, CTP and the correct spin–statistics relationship The parallel work of Rühl on $SL(6,C)$ is not mentioned. The groups $U(6) \times U(6)_{\gamma_0}$ and $SU(6)_W$ for the Strong interaction emerge rather unconvincingly as subgroups of the algebra produced by commuting the Weak currents The successes of the theory are presented, but I failed to find the bad results (Hussein and Rotelli, Winternitz *et al*) on $p\bar{p}$ annihilation at rest. Fortunately, as explained above, the formulation of this theory is not as important for the progress of physics as the solution of the questions which it raises The problem of the hadron spectrum still stands where it did in the late summer of 1966, when the manuscript of this book was completed P T MATTHEWS

LIQUID STATE PHYSICS

An Introduction to the Liquid State

By P. A Egelstaff Pp. xvi+236. (London· Academic Press, Inc (London), Ltd , New York Academic Press, Inc , 1967.) 57*s*. 6*d* ; $10

THE last decade has seen the creation of a subject that may be called liquid state physics, and this book is one of the first to attempt an account of the new field.

X-ray and neutron diffraction have been used for many years to study the equilibrium structures of solids and, less frequently, of liquids Recent improvements in the accuracy of the work on liquids, recent advances in equilibrium theory, and the use of computers for simulation experiments have at last brought some order into what was previously a confusing situation. We can now claim to have some degree of quantitative understanding of the structure and thermodynamic properties of simple liquids

These advances are described by Egelstaff in the first ninety pages of this book, but it is clear that his real interest is in the dynamic properties. These can be studied in experiments of neutron and optical scattering in which the change of energy and angle of a monochromatic beam is observed The incoherently and coherently scattered neutrons are related, respectively, to the evolution in time of the distribution functions of single molecules and of molecular pairs It is the uncompleted task of non-equilibrium statistical mechanics to relate the space, time and velocity distribution functions to the transport properties of a fluid

These advances of technique and theory have come mainly from those who both have access to powerful sources of neutrons, and have done theoretical work on the parallel problems in solid state physics In this country these conditions have been met at Harwell where Egelstaff and his colleagues have been amongst the most successful both in obtaining and interpreting new results

The liquids discussed in this book are mainly "single particle" fluids, such as the inert gases and liquid metals, although the author spares a few pages for other problems

—molecular fluids, quantal fluids and even for a brief discussion of the critical point. These pages are very few, and might have been better used to allow less terse accounts of the main subjects

The book is far from elementary, in spite of its title The author explains in his preface that it arose from a course of lectures to postgraduate physicists, and it is unfortunate that the publishers' summary on the dust jacket claims that it is suitable for undergraduates The subject is inherently difficult, but those who have heard the superb reviews that the author has given at more than one conference will not be surprised by the many ingenious diagrams and other aids that he uses to mitigate these difficulties The book is recommended to those who are willing to work hard at it

J S ROWLINSON

TWO ON FLUID DYNAMICS

An Introduction to Fluid Dynamics

By Frank Chorlton Students' paperback edition. Pp University Press, 1967) 75*s* net; $13 50

Textbook of Fluid Dynamics

By Frank Chorlton Students' paperback edition Pp xiv+399 (London D Van Nostrand Company, Ltd , Princeton, N J D Van Nostrand Company, Inc , 1967) 35*s*

THE longevity of fluid mechanics as a scientific discipline is due primarily to the multitude of applications of the same basic ideas and partly because the correct interpretation of the theory is frequently not intuitively obvious. The experimenter is continually challenging fundamental tenets of the theoretician to the advantage of both and to the lasting benefit of the discipline These features of fluid mechanics, however, make the writing of introductory texts extremely difficult, for the author has to steer a narrow course between a phenomenological approach, in which the actual behaviour of fluids is properly described but the theory is presented in a piecemeal and unconvincing manner, and a mathematical approach in which emphasis is laid on elegant solutions of the basic equations without consideration of their relevance to observation.

Only a few books written this century have managed to achieve a proper balance and their authors have in consequence become household names in the world of fluid mechanics—Lamb, Goldstein, Prandtl Let me say at once that the new book by Professor Batchelor is truly worthy of standing next to them on the shelf of honour No instructor of an elementary course in fluid dynamics will be able to prepare his lectures without first seeing what Batchelor has to say about it, lest his students repair the omission for him The book is firmly embedded in the realities of fluid dynamics, but nevertheless the author develops the mathematical arguments in a coherent way so that the novice applied mathematician will feel that there is an important part for him to play in the discipline

The author rightly confines himself almost entirely to the study of incompressible fluids in laminar motion, examining in depth the significance of the interplay between inertial, pressure and viscous forces The opening chapter, however, on the physical properties of fluids, examines a wider spectrum and in some ways is slightly less satisfying than the remainder—no doubt because the author has to compress a number of complicated theories, such as thermodynamics, into a very few pages After that introduction the book gets properly under way with the kinematics of flow, governing equations, viscous effects at small and large Reynolds number, irrotational inviscid flow, and ending up with a study of inviscid rotational flow which includes a considerable section on fluids having a rigid rotation at infinity The explanation is careful, the style is pellucid and the diversity, excitement and beauty of the subject are made manifest to the reader The book includes a number of examples, some of which most students might find intimidating and the instructor may well have to supplement them with a set of his own

Alternatively he might turn to the extensive set in Dr Chorlton's book This second book under review is entirely mathematical in content and I could detect no comparison at any stage with experiment. The dangers of this approach have already been referred to and the author can be criticized for over-emphasizing mathematical beauty at the expense of physical truth However, provided the instructor emphasizes the physics of fluid mechanics his students will find Chorlton's book useful, for it presents the mathematical arguments in a clear and concise way

K STEWARTSON

HEREDITY AND CANCER

Hereditary Factors in Carcinoma

By Henry T Lynch (Recent Results in Cancer Research, Vol 12.) Pp xiv+186 (Berlin and New York Springer–Verlag, 1967) 24 DM ; $6.

As early as the seventeenth century, the physician Hoffmann suggested that a disposition to cancer might be inherited, basing the suggestion on family histories with a high incidence of malignant disease. The enquiry conducted by the Society for the Investigation and Cure of Cancer in 1802 asked the physicians in this country "Is cancer inherited ?" which shows that such a possibility had already been considered by then. Throughout the nineteenth century many family pedigrees were reported in which several members died from cancer; these reports formed the basis of statistical investigations into the familial tendencies of the disease These studies, however, were incomplete, lacking a suitable control group for comparison, and were useless It is not surprising that owing to the unreliability of the data and the contradictory conclusions which had been drawn from their investigations, the clinicians were inclined to dismiss heredity as a possible factor in the development of cancer.

Recent enquiries into the familial incidence of malignant conditions are conducted on a truly scientific basis; the pedigree studies employ improved statistical methods and use more vigorous criteria in selecting the control groups What are the findings of these investigations ? The monograph under review is based on more than 700 reports published in the world literature which deal either directly or indirectly with the subject of "cancer genetics". The aim of the author is to bring together the evidence which supports a "genetic etiology" at least in some human malignancies The classical examples of those pathological conditions which are known to be inherited (for example, xeroderma, multiple polyposis of the intestine) and result in cancer are given prominence. Much information concerning the common types of cancer, such as breast, stomach and lung cancer, has been brought together, and the author stresses the increased risk which a high incidence of these cancers in the families indicates, for example, the risk is claimed to be fourteen times higher for a smoking member of a family in which another member had cancer

The monograph contains a brief summary of the author's study concerning the incidence of multiple cancer in fifty families, six of which are presented in more detail. He finds an incidence of 19 per cent as compared with 3 per cent in the control group and draws the conclusion that the "multiple cancer syndrome" has a genetic basis According to him an autosomal dominant gene is acting together with environmental factors The reader of the monograph is advised to consult the original reports which give more information about the respective role of the familial and environmental factors in the development of a particular malignant disease.

The true value of the monograph is that it serves as a rich source of information covering many and varied aspects of cancer which are related to heredity.

P. C. KOLLER

VIRUSES AND DISEASE

Clinical Virology

By R. H. A. Swain and T. C. Dodds. Pp. xii+318. (Edinburgh and London: E. and S. Livingstone, Ltd., 1967.) 75s. net.

WHEN so much virology is directed towards molecular biology, it is worth recalling that the first impetus in the study of viruses came from the investigation of disease. Nor can it yet be said that problems associated with virus infections no longer confront us. Viruses which are capable of inducing disease in some can be isolated on occasion from others who are perfectly healthy. Some viruses appear to have such growth requirements that it has not yet been possible to find a suitable substrate other than the human or animal host. As for the suppression of virus multiplication by drugs, only the fringe has been reached.

The appearance of this book, which sets out to correlate known facts on the aetiology, clinical manifestations, pathological effects and epidemiology of virus diseases affecting man, is timely. It should be useful both to students seeking basic information and graduates facing problems of diagnosis and the general handling of such diseases. The information provided is clearly set out and easy to read. It is concise but on the whole adequate for its purpose. Those who wish to read further are given guidance at the end of each chapter. There is an impressive array of charts and photographs, many in colour, in support of the aim to supplement mere words by illustration. This adds to the attractiveness of the book.

There are four sections, the first two comprising the major part. Respectively, these are concerned with (1) general considerations of viruses, their characters and properties, together with some of the standard procedures used in the study of newly isolated strains and for the related immunological tests, (2) descriptions of virus diseases affecting different systems of the body, the virus groups concerned, and the methods by which they are identified. The slowness of virus laboratories in reporting results of investigations is a worry to clinicians. The information given here may help towards a better understanding of laboratory problems. At the same time there is continual pressure for more rapid diagnostic tests and in a still developing subject a book does not contain all the latest information. For example, in the diagnosis of rubella, important because of its association with congenital deformity, there is no mention of the simple and rapid haemagglutination–inhibition test.

Section three deals with infections caused by bedsoniae, the group which includes psittacosis, lymphogranuloma venereum, trachoma and inclusion conjunctivitis, and the rickettsiae. Of the latter only Q fever is prevalent in Britain, but no reference to studies carried out here is quoted. In section four on the control of infections there is useful information on active immunization including schedule guides for babies and international travellers. There is also an account of the state of chemotherapy in virus diseases.

No book is free from errors or omissions. On page 176 is the surprising statement that there are thirty-two Coxsackie A serotypes. Some of the references have careless spelling faults, and a reference to a British manual of virus methods would have been helpful. Despite such mild criticism this should be a very useful book.

A. D. MACRAE

RESEARCH ON PROTOZOA

Research in Protozoology

In four volumes. Edited by Tze-Tuan Chen. Vol. 1. Pp. vii+428+16 plates. (Oxford, London and New York: Pergamon Press, Ltd., 1967.) 110s. net.

IN 1941 a collection of review articles edited by G. N. Calkins and F. M. Summers was published under the title *Protozoa in Biological Research*. It resulted from the co-operative endeavour of a number of protozoologists concerned about "the best means to stimulate further research on these unicellular animals". For twenty-five years "Calkins and Summers" has remained an authoritative work of reference covering a wide range of research studies on the protozoa. In *Research in Protozoology* the editor has set out to survey the progress of studies on protozoa in the quarter of a century since the earlier book by presenting a series of review articles spread over four volumes and covering the principal aspects of protozoan biology. This is a formidable undertaking, for the 1941 book comprised some twenty articles occupying 1,150 pages, and the spectacular advances in recent years in such fields as biochemistry and ultrastructure studies have had far-reaching effects on every aspect of protozoological research.

Reviews written for such a purpose might be expected to bring all aspects of a particular topic together, so that a biologist with only a general knowledge of protozoology may be able to gain a broad understanding of the subject; they might also be expected to extend up to the frontiers of current knowledge in the subject so that a research worker, perhaps in a closely allied field, may be able to find his way around the recent literature with confidence. To do both of these in the same article is a difficult task, and becomes more difficult as the scope of the article is extended. This is clear in the present volume where the articles with narrow subject limits can be comprehensive works for reference as well as being useful for teaching, but there is a tendency for the wide-range subjects to become little more than reference lists which mean little to anyone without a good knowledge of protozoology and an extensive reference library. There are periodicals which publish review papers whose function appears to be the provision of up to date reference lists, but the articles in a book such as this, if they are to stand the test of time, should be more or less comprehensible by themselves, and should therefore contain adequate explanations and illustrations.

The first of the five articles in this volume is by Everett Anderson and deals with a restricted range of aspects of the fine structure of protozoa, namely, a miscellany of cytoplasmic inclusions and those cytoplasmic organelles that are of membranous construction. Such structures as cell surface membranes and their modifications, cell walls, fibrous structures and nuclei will presumably be dealt with in later volumes. Dr Anderson gives the reader a fair impression of the information available in this field up to 1964, although he only quotes a small proportion of the relevant literature on the subject. The chapter includes twenty-four micrographs which illustrate more or less convincingly the structures described.

The article on "Motile Behaviour of Protozoa" by Theodore Jahn and Eugene Bovee occupies 160 pages and lists more than 1,000 references—it is almost a book in itself. The scope of the subject matter is so wide that even with this extensive treatment it was not possible to do justice to some aspects of protozoan motility; many things are inadequately explained and there are no illustrations at all in most sections of the chapter. There are clearly arguments in favour of attempting to integrate all information on the movement of protozoa within a single framework, but this material would fit better into the pattern of this sort of review if it had been broken up into several chapters covering such aspects as "Motor responses of protozoa" (comparable with the review by Mast in the 1941 volume), "Movement of protozoa by flagella, cilia and other fibrous organelles" and "Movement of protozoa by cytoplasmic streaming" There is an immense amount of information in this chapter, and Jahn and Bovee have produced an excellent guide to the literature, although the omission of such structures as haptonemata and axostyles from their account of motile organelles is regretted

In his review of "Respiratory Metabolism" William Danforth has given an admirable general introduction and followed this by a systematic survey of our knowledge of respiration in protozoa It is admitted that evidence is mostly too scanty for generalizations, which makes it more difficult to convey the information coherently The author makes it plain that protozoa have exploited this aspect of their biology to an extent comparable with that known for more overt features, and his article is a valuable source of information about the common laboratory species Dr Danforth must be disappointed that his article was delayed in publication, for his literature review was completed in mid-1963

Problems of osmotic regulation, ionic regulation and excretion, with special reference to the functions of contractile vacuoles, are discussed in a comprehensive and authoritative, but commendably brief, chapter by J A Kitching The author has taken pains to illustrate his article with well-chosen figures and micrographs, and the reader is led to feel that he can really understand what is known of the subject from this chapter alone

Information on "Nutrition and Growth of Protozoa", reviewed by R P Hall in the last article, must necessarily overlap parts of the article on respiratory metabolism, but it is valuable to see such information dealt with from different viewpoints in the two chapters Parts of Hall's chapter make rather dull reading, with lists of species which have been shown to require various minerals or growth factors; surely this information could have been given adequately in tables, and the author could have spent more time discussing such aspects as the sources and uses of the required materials There is a great deal of useful information in this chapter, but it could have been presented in a more palatable form

This book clearly must be present in every protozoological library, but it could have been made more widely useful in teaching as well as research if more thought had been given to the subject divisions and the method of presentation, it would then be a book that every protozoologist should have on his personal bookshelf The problem of keeping a library provided with information about research in protozoology could be solved more adequately by annual or biennial volumes of shorter review articles which would allow topics to be reviewed as frequently as advances in that topic demand, and could provide a more rapid means of publication The present attempt to produce a comprehensive contemporary review of protozoological research appears from the first volume to be only partially successful; it is to be hoped that the future volumes will contain articles as good as the best in this first volume

M A SLEIGH

EUGLENA AND ITS RELATIVES

Euglenoid Flagellates

By Gordon F Leedale (Prentice-Hall Biological Sciences Series) Pp xiii + 242 (Englewood Cliffs, N J, and London · Prentice-Hall, 1967) 56*s*

AFTER having been for a long time a type in elementary courses in both botany and zoology, *Euglena* still features in modern biological teaching At the same time, it continues to be the subject of advanced research in a variety of fields, notably the biochemistry of vitamin B_{12}, the role of non-nuclear DNA, and photoreception Its position in biology must surely be unique, and this book, which surveys *Euglena* and its relatives, therefore promises to be correspondingly useful

About one third of the book is devoted to the consideration of the position of euglenoid flagellates in the biological hierarchy and to matters of taxonomy. The system of classification presented is a revised one based, unfashionably but quite plausibly, on a phylogenetic scheme The characters of order and genera are described and illustrated by clear line drawings Together with a dichotomous key given as an appendix, these provide an introduction to the taxonomy which can readily be extended by means of the references given. A valuable feature is the inclusion of notes on individual species indicating, among other things, which are available in culture

The second part of the book deals with cytology and fine structure This is lavishly illustrated with original photomicrographs and electron micrographs which, as one would expect from an associate of Professor I Manton, are all of excellent quality The various cell components, including pellicle, flagella, Golgi bodies, mitochondria and chloroplasts, are described clearly and concisely, examples being taken from many different genera The inclusion of both light photomicrographs and electron micrographs of these various structures should be particularly useful to the teacher Their function is touched on but not dealt with *in extenso* (physiological aspects were reviewed by J J Wolken in his book *Euglena an Experimental Organism for Biochemical and Biophysical Studies*, 1961)

This book can be unreservedly recommended, both to the teacher wishing to refurbish his image of a familiar type and to the research worker seeking background information about his experimental organism Both will be stimulated to find out more about this fascinating group, among the members of which are a great variety of physiological types providing excellent material for the investigations of problems suited to tastes ranging from that of the ecologist to that of the molecular biologist

G. E FOGG

JUNIOR ENGINEERING

The Engineer in Wonderland

By E R Laithwaite Pp viii + 172 (London The English Universities Press, Ltd, 1967) 27*s* 6*d* net

IT was a clever stroke to ask Professor Eric Laithwaite of Imperial College to give the 1966 Christmas Holiday Lectures for schoolchildren at the Royal Institution Here was an engineer full of enthusiasm for his subject, yet able to make it comprehensible Publishing the lectures as a book might have been a much worse idea, but it has come off splendidly well—the book has a pace and excitement which a collection of essays would find it hard to match It is also very well illustrated.

For the first time, the 1966 lectures were televised by the BBC, and, as Professor Laithwaite points out, were seen by more people than had attended all the previous 136 series of lectures The subject of the lectures, each of which had as a title a quotation from *Alice in Wonderland*, was electromagnetic induction, still a fascinating subject despite the ubiquity of its applications Professor Laithwaite described and demonstrated a variety of electric motors of odd shapes and sizes, including the linear motor It is interesting, perhaps, that he does not claim that the linear motor will be cheaper than other forms of power It will, he says, be more reliable, having no moving parts, and this will come to have a much greater economic importance in the future Reliability will be the crucial factor in the twenty-first century, replacing efficiency and power factor as the quality engineers strive for

The most exciting moment in the series of lectures came when Professor Laithwaite and his colleagues succeeded for the first time in levitating a hollow aluminium sphere

30 in in diameter. Professor Laithwaite was determined to accomplish this for the first time in the lecture theatre of the Royal Institution, to make up for a disappointment five years earlier. Then, he writes, he had been asked to give a Friday evening discourse and had decided to try a new experiment, levitating a flat rectangular plate Difficulties with winding the coils had finally persuaded him not to proceed, but when he returned to the laboratory and carried out the experiment, he discovered that if he had gone on, the experiment would not only have succeeded but would have demonstrated a new phenomenon for the first time This disappointment made him determined to succeed with the large sphere, and how it was finally done makes an interesting chapter on its own. He used two coils, one inside the other, with the outer coil raised slightly above the level of the inner one

As befits lectures intended for schoolchildren, these contain little mathematics Particularly valuable for teachers are short appendices describing how the models can be made, and the book is likely to find a place in many school laboratories. Nigel Hawkes

University News : London

Professor P. J B Clarricoats, professor of electronic engineering in the University of Leeds, has been appointed to the second chair of electrical engineering tenable at Queen Mary College

Appointments

Professor M G P Stoker, at present professor of virology in the University of Glasgow and director of the Medical Research Council Experimental Virus Research Unit, has been appointed director of research of the Imperial Cancer Research Fund, in succession to Dr G F Marrian

Dr E M Thain has been appointed deputy director of the Tropical Products Institute

Announcements

The Steacie Prize for 1967 has been awarded to Professor Myer Bloom of the Department of Physics, University of British Columbia, for his work in molecular physics The prize, which consists of a cash award of $1,500, is named after the late Dr E W R. Steacie, who was president of the National Research Council of Canada between 1952 and 1962.

The committee set up by the Secretary of State for Education and Science, Mr Patrick Gordon Walker, to look into the organization of British national libraries has now had its first meeting The committee, under the chairmanship of Dr F S Dainton, Vice-Chancellor of the University of Nottingham, is considering how best to develop a comprehensive library system for Britain Its first request has been to ask interested individuals or groups to submit evidence, in the first place in writing. The committee is particularly interested in factual information about the adequacy and utilization of existing library facilities, and about the pattern of future demand for libraries Evidence on these or related matters should be sent to Dr N B W Thompson, Secretary, The National Libraries Committee, Curzon Street House, Curzon Street, London, W1, not later than April 30, 1968

The trustees of the Lady Tata Memorial Trust invite applications for fellowships and scholarships for research on leukaemia in the academic year beginning October 1, 1968 In view of the affinity between leukaemia and other forms of neoplastic disease, candidates with programmes of research on any aspect of malignant disease which may throw light on problems of leukaemia will be eligible for consideration The awards are open to suitably qualified investigators of any nationality, working either in their own institutions or in other centres abroad Further details can be obtained from the Secretary of the (European) Scientific Advisory Committee, Lady Tata Memorial Trust, Chester Beatty Research Institute, Fulham Road, London, SW3)

Meetings

Newer Methods and Concepts of Polymerization, February 23–24, University of Bradford (The Registrar, University of Bradford, Bradford 7)

Analytical Chemistry and Applied Spectroscopy, March 3–8, Pittsburgh (Dr John O Frohliger, Department of Occupational Health, Graduate School of Public Health, University of Pittsburgh, Pittsburgh, Pennsylvania 15213)

Semimetals and Narrow Gap Semiconductors, April 2–4, University of Durham (The Meetings Officer, The Institute of Physics and the Physical Society, 47 Belgrave Square, London, SW1)

Israel Physical Society special meeting, April 14–15, Hebrew University of Jerusalem (Mrs R. Rahman, Faculty of Science, The Hebrew University of Jerusalem, Israel)

Stereochemistry, April 28–May 4, Burgenstock (Professor J Sicher, Institute of Organic Chemistry and Biochemistry, Czechoslovak Academy of Science, Flemingovo n 2, Praha 6)

Protides of Biological Fluids, May 4–5, Bruges (XVIth Colloquium on Protides of Biological Fluids, PO Box 71, Brugge 1).

Thyroid Cancer, May 8–10, Lausanne (Professor G Candardjis, Chairman of the Organizing Committee, Institut Universitaire de Radiologie Médicale, Hôpital Cantonal, 1005 Lausanne)

Continuous Cultivation of Micro-organisms, June 17–23, Prague (Dr Zdeněk Fencl, Head of the Department of Technical Microbiology, Institute of Microbiology, Budějovická 1083, Prague 4)

Microcirculation, June 24–29, Gothenburg (Professor Lars-Erik Gelin, Surgical Department 1, Sahlgrenska Sjukhuset, Gothenburg SV)

Erratum In the review of *Sex Chromosomes and Sex-linked Genes* by Dr Susumu Ohno (*Nature*, **216**, 891, 1967) the price of the book was misquoted at $95; it should be $9.50.

Erratum In the article "Regulation of Cytochrome Oxidase in Human Cells in Culture" by N Hakami and D A. Pious (*Nature*, **216**, 1087; 1967) the position of the words "aerobic" and "anaerobic" in Fig 1 should be reversed

Erratum In the communication "Cosmological Models containing both Radiation and Matter" by C B G McIntosh (*Nature*, **216**, 1297; 1967) equation (21) on page 1298 should read $t = \frac{2}{3}\frac{AB}{c}\{\varepsilon^{-3/2}(1-9\varepsilon) + 6\sqrt{3}\}$ (B = constant) Equation (24) should read $\rho_{r,0} = 6\ 8 \times 10^{-34}$ gm/cm^3 and equation (25) should read $\varkappa\rho_r c^4 = 9H^2\varepsilon$

Erratum In the communication "Radio Sources in Opposite Directions as a Cosmological Test" by Jan-Erik Solheim (*Nature*, **217**, 41, 1968) the fourth sentence of the legend to Fig 1 should read "The two models shown are based on a Hubble parameter $H_0 = 100$ km sec^{-1} Mparsec^{-1}, q_0 is the deceleration parameter and σ_0 a density parameter, $\sigma_0 = 4\pi G\sigma_0/3H_0^2$ where σ_0 is the mean density of the universe "

FORTHCOMING EVENTS

(Meetings marked with an asterisk are open to the public)

Monday, January 15

INSTITUTION OF ELECTRICAL ENGINEERS (at Savoy Place, London, WC2), at 5 30 p m —Discussion Meeting on "Project Problems" opened by Mr A Draper

Tuesday, January 16

SOCIETY OF CHEMICAL INDUSTRY, FOOD GROUP AND AGRICULTURE GROUP (at 14 Belgrave Square, London, SW1), at 10 30 a m —Symposium on "Apples"

INSTITUTION OF ELECTRICAL ENGINEERS (joint meeting with the Electronics Group of the Institute of Physics and the Physical Society, at the Institution of Electrical Engineers, Savoy Place, London, WC2), at 2 30 p m —Colloquium on "M O S T Devices"

UNIVERSITY OF ASTON IN BIRMINGHAM (at Gosta Green, Birmingham, 4), at 5 30 p m —Professor D Hinton "Master of Science or Mistress of Arts ?" (Inaugural Lecture)

SOCIETY OF CHEMICAL INDUSTRY, HEAVY ORGANIC CHEMICALS GROUP, and the PLASTICS AND POLYMER GROUP (at 14 Belgrave Square, London, SW1), at 6 p m —Mr C E Hollis "Chloroprene and Polychloroprene"

Wednesday, January 17

INSTITUTION OF ELECTRICAL ENGINEERS (at the Royal Aeronautical Society, 4 Hamilton Place, London, W1)—Colloquium on "Fault Analysis in the Design of Complex Systems"

INSTITUTE OF NAVIGATION (at the Royal Institution of Naval Architects, 10 Upper Belgrave Street, London, SW1), at 2 15 p m —Dr W P Williams "Sub-Surface Navigation"

ROYAL STATISTICAL SOCIETY (at the London School of Hygiene and Tropical Medicine, Keppel Street, Gower Street, London, WC1), at 5 15 p m —Dr M G. Kendall "The Future of Statistics"

INSTITUTION OF ELECTRICAL ENGINEERS (at Savoy Place, London, WC2), at 5 30 p m —Mr B J Rogers "Colour Television Receiver Design"

INSTITUTION OF MECHANICAL ENGINEERS, MANUFACTURE AND MANAGEMENT GROUP (at 1 Birdcage Walk, Westminster, London, SW1), at 6 p m —Discussion on "Mathematics for Management"

SOCIETY OF ENVIRONMENTAL ENGINEERS (in the Mechanical Engineering Department, Imperial College, London, SW7), at 6 p m —Mr M J B Shelton "Dust"

INSTITUTION OF ELECTRICAL ENGINEERS, LONDON GRADUATE AND STUDENT SECTION (at Savoy Place, London, WC2), at 6 30 p m —Mr E M N Fitzgerald and Mr S A Marshall "The Simulation and Control of Steam Turbines"

OIL AND COLOUR CHEMISTS' ASSOCIATION, LONDON SECTION (in the New Engineering Block, University College, Gower Street, London, WC1), at 6 30 p m —Mr T R Bullett and Mr D Dasgupta "Characterization of Blast Cleaned Surfaces and Its Relation to Paint Performance".

SOCIETY FOR ANALYTICAL CHEMISTRY, MICROCHEMICAL METHODS GROUP (at "The Feathers", Tudor Street, London, EC4), at 6 30 p m —Discussion Meeting on "Pyrolysis"

Wednesday, January 17—Thursday, January 18

INSTITUTE OF PHYSICS and the PHYSICAL SOCIETY, MATERIALS AND TESTING GROUP, OPTICAL GROUP, and the STRESS ANALYSIS GROUP (at the National Physical Laboratory, Teddington, Middlesex)—Conference on "Holography—Recent Advances and Applications"

Thursday, January 18

CHEMICAL SOCIETY (in the Large Chemistry Lecture Theatre, University College, Gower Street, London, WC1), at 2 30 p m —Symposium on "Developments in Transition Metal Chemistry"

INSTITUTION OF ELECTRICAL ENGINEERS (at Savoy Place, London, WC2), at 2 30 p m —Discussion Meeting on "Co-ordination of Thermal Ratings of Transmission Plant"

INSTITUTION OF MINING AND METALLURGY (at the Geological Society, Burlington House, Piccadilly, London, W1), at 5 p m —Scientific Papers

LINNEAN SOCIETY OF LONDON (at Burlington House, Piccadilly, London, W1), at 5 p m —Dr P E Brandham "Movement of Algae", Dr Edward J Klekowski, jun "General Considerations of Fern Mating Systems"

INSTITUTE OF PETROLEUM (at 61 New Cavendish Street, London, W1), at 5 30 p m —Mr T K Tylko "Possible Applications for the Plasma-Arc in the Oil Industry".

INSTITUTION OF MECHANICAL ENGINEERS, APPLIED MECHANICS GROUP (at 1 Birdcage Walk, Westminster, London, SW1), at 6 p m —Discussion on "Unusual Mechanisms and Linkages"

SOCIETY OF CHEMICAL INDUSTRY ROAD AND BUILDING MATERIALS GROUP (at 14 Belgrave Square, London, SW1), at 6 p m —Dr T W Parker "The Philosophy of Assessment and Its Relation to Testing in the Agrement Scheme"

PHARMACEUTICAL SOCIETY OF GREAT BRITAIN (at 17 Bloomsbury Square, London, WC1), at 7 p m —Mr L Wilson "Scientific and Technical Information—Millstone or Keystone ?"

ROYAL SOCIETY OF TROPICAL MEDICINE AND HYGIENE (at Manson House, 26 Portland Place, London, W1) at 7 30 p m —Sir John Boyd, OBE, FRS address on the occasion of the centenary of the birth of Sir Leonard Rogers, FRS Dr D Morley "Factors Influencing Growth and Nutritional Status of Infants and Young Children in a Nigerian Village"

Friday, January 19

SOCIETY OF CHEMICAL INDUSTRY, FINE CHEMICALS GROUP (at 14 Belgrave Square, London, SW1), at 6 30 p m —Dr J M Sprague (USA) "Recent Advances in Diuretics"

Monday, January 22

INSTITUTION OF ELECTRICAL ENGINEERS (at Savoy Place, London, WC2), at 10 a m. Colloquium on "Microwave Integrated Circuits", "Microwave Solid State Sources"

INSTITUTE OF ACTUARIES (at Staple Inn Hall, High Holborn, London, WC1), at 5 p m —Mr H A R Barnett "A Theory of Mortality".

INSTITUTION OF ELECTRICAL ENGINEERS (at Savoy Place, London, WC2), at 5 30 p m —Discussion Meeting on "Microwave Electrostatic Wattmeter" opened by Professor H E M Barlow, FRS

UNIVERSITY OF LONDON (in Lecture Theatre A, Mechanical Engineering Building, Imperial College of Science and Technology, Exhibition Road, London, SW7), at 5 30 p m —Professor Bertil Matern (Royal School of Forestry, Stockholm) "Statistical Models of Two-Dimensional Variation" (further lectures on January 24 and 26) *

ROYAL SOCIETY OF ARTS (at John Adam Street, Adelphi, London, WC2), at 6 p m —Mr W B Gosney "Modern Refrigeration" (First of three Cantor Lectures Further lectures on January 29 and February 5)

APPOINTMENTS VACANT

APPLICATIONS are invited for the following appointments on or before the dates mentioned

PRINCIPAL LECTURER in the DEPARTMENT OF CHEMISTRY AND BIOLOGY —The Principal, Barking Regional College of Technology, Longbridge Road, Dagenham, Essex (January 20)

LECTURER or JUNIOR LECTURER (preferably with a special interest in soil mycology) IN MYCOLOGY—The Secretary, Trinity College, Dublin 2, Republic of Ireland (January 24)

LECTURER (preferably with experience in non-numerical computing) in the DEPARTMENT OF MATHEMATICS in the field of computational mathematics—The Registrar, The University, Nottingham (January 29)

SENIOR LECTURER or LECTURER IN THE DEPARTMENT OF ZOOLOGY, University of Ibadan, Nigeria—The Inter-University Council, 33 Bedford Place, London, WC1 (January 29)

DIRECTOR OF THE HILL FARMING RESEARCH ORGANIZATION—Professor S J Watson, Edinburgh School of Agriculture, West Mains Road, Edinburgh 9, Scotland (January 31)

LECTURER IN PHYSICAL CHEMISTRY at the University of New South Wales—The Association of Commonwealth Universities (Branch Office), Marlborough House, Pall Mall, London, SW1 (Australia and London, January 31)

LECTURER and a SENIOR DEMONSTRATOR in the DEPARTMENT OF ZOOLOGY —The Registrar and Secretary, University of Durham, Durham City (February 3)

LECTURER IN EDUCATION at the University of Western Australia—The Association of Commonwealth Universities (Branch Office), Marlborough House, Pall Mall, London, SW1 (Australia and London, February 3)

LECTURER or ASSISTANT LECTURER IN PHYSIOLOGY—The Registrar, The University, Sheffield (February 3)

LECTURER or SENIOR LECTURER IN CHEMISTRY at the University of Tasmania—The Association of Commonwealth Universities (Branch Office), Marlborough House, Pall Mall, London, SW1 (Australia and London, February 5)

ASSOCIATE PROFESSOR IN CLINICAL BACTERIOLOGY IN THE FACULTY OF MEDICINE, University of Sydney, Australia—The Association of Commonwealth Universities (Branch Office), Marlborough House, Pall Mall, London, SW1 (Australia and London, February 9)

JUNIOR LECTURER IN MATHEMATICS (Pure or Applied)—The Secretary of Faculties, University Registry, Broad Street, Oxford (February 12)

CHAIR OF CHEMICAL TECHNOLOGY in the DEPARTMENT OF CHEMISTRY, University of Malaya—The Association of Commonwealth Universities (Branch Office), Marlborough House, Pall Mall, London, SW1 (Kuala Lumpur and London, February 15)

CHAIR OF PHARMACOLOGY at the MEDICAL FACULTY OF ROTTERDAM—Professor B Leijnse, Wytemaweg 2, Rotterdam, The Netherlands (February 15)

DEPUTY LIBRARIAN (with academic and professional qualifications) at Victoria University of Wellington, New Zealand—The Association of Commonwealth Universities (Branch Office), Marlborough House, Pall Mall, London, SW1 (New Zealand and London, February 15)

ASSISTANT LECTURER/LECTURER (with postgraduate experience in the theory and use of microwaves or solid-state microwave devices) IN ELECTRONICS—The Secretary, University of Lancaster, University House, Bailrig, Lancaster, quoting Ref L 270/C (February 16)

TURNER AND NEWALL RESEARCH FELLOWS IN CHEMISTRY, PHYSICS, GEOLOGY, MINERALOGY, METALLURGY, APPLIED MATHEMATICS, ENGINEERING, MEDICINE, or related technologies—The Academic Registrar, University of London, Senate House, London, WC1 (February 16)

READER IN PHYSIOLOGY—The Registrar, University of Newcastle upon Tyne, 6 Kensington Terrace, Newcastle upon Tyne, 2 (February 19)

LECTURER (preferably interested in the mechanical behaviour of materials) IN METALLURGY, Wollongong University College, University of New South Wales—The Association of Commonwealth Universities (Branch Office), Marlborough House, Pall Mall, London, SW1 (Australia and London, February 26)

ASSOCIATE PROFESSOR (Reader), SENIOR LECTURER or LECTURER (two positions) in the ZOOLOGY DEPARTMENT, University of Otago, Dunedin, New Zealand—The Secretary-General, Association of Commonwealth Universities (Branch Office), Marlborough House, Pall Mall, London, SW1 (New Zealand and London, February 29)

ASSOCIATE PROFESSOR (preferably anatomist, with teaching experience in both gross anatomy and neuro-anatomy) in the DEPARTMENT OF ANATOMY—Head, Department of Anatomy, Faculty of Medicine, University of Ottawa, 275 Nicholas Street, Ottawa, Ontario, Canada

CHEMIST (with an interest in gas chromatography) to join a team working on metabolic disorders in children—The Chemical Pathologist, Hospital for Sick Children, Great Ormond Street, London, WC1

MYCOLOGIST (graduate in botany or agricultural botany with experience in plant pathology or mycology) in the POTATO BRANCH—The Acting Secretary, National Institute of Agricultural Botany, Huntingdon Road, Cambridge

SENIOR LECTURER or LECTURER IN PHYSICS—The Secretary, Queen's University, Belfast, Northern Ireland

HOW TO BUY NATURE

Volumes start in January, April, July and October, but subscriptions may begin with any issue

The direct postal price per subscription for one or two copies of NATURE each week is

***12 MONTHS** (52 issues and 4 indexes)

Great Britain and Eire		**£14.0 0** each
United States of America	(by air freight)	**$48** each
Canada	(by air freight)	**$52** each
Elsewhere overseas by surface mail		**£14.0 0** each

(Charge for delivery by air mail on application)
*Shorter periods *pro rata* (Minimum three months)

MULTIPLE SUBSCRIPTIONS

For subscribers who take more than two copies of NATURE each week these reduced annual rates are offered

12 MONTHS (52 issues and 4 indexes)

Number of Copies	*G B & Eire*	*U S A*	*Canada*	*Elsewhere (surface mail)*
		(by air freight)		
	Each	*Each*	*Each*	*Each*
3–5	**£13 10 0**	**$46 50**	**$50 50**	**£13.10 0**
6–11	**£12.15 0**	**$44.50**	**$48 30**	**£12.15 0**
12 or more	**£12 0 0**	**$42 50**	**$46 00**	**£12.0.0**

Multiple subscriptions must run concurrently Every copy will be posted separately, and for speed of delivery each subscription can be addressed to a different individual, or department at the same address (ZIP essential for U S A.)

WHY...

do more Scientists every day use Phoenix Amino Acid Analyzers?

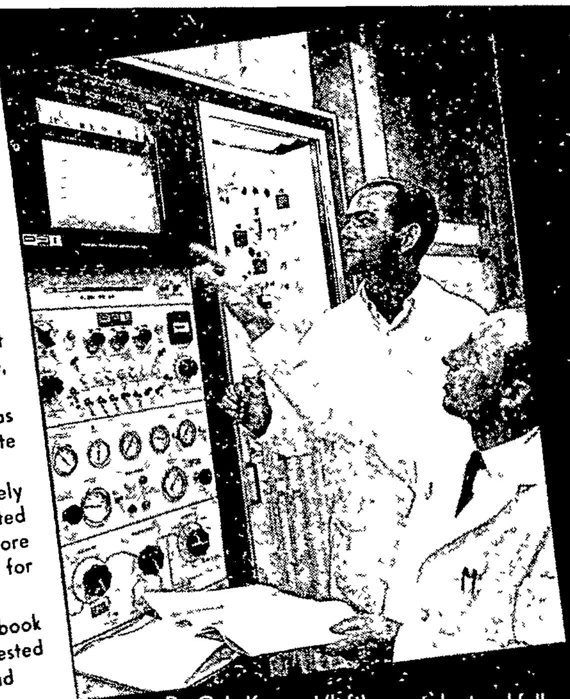
Because Phoenix manufactures the most complete line of Amino Acid Analyzers available today

Continued improvements and refinements, over the past decade, have made Phoenix Analyzers more versatile, more flexible, and more adaptable

This is why more scientists have specified Phoenix as their instrument of choice for faster and more accurate analyses

Whether your requirement is for a small, relatively inexpensive bench-type analyzer or a large sophisticated dual-model instrument capable of performing more complex functions, Phoenix has the right analyzer for every need

A new 110 page Liquid Chromatography Handbook prepared by Phoenix, is now available to the interested researcher Write for your free copy on your letterhead



Dr. C. L. Keswani (left) a post-doctoral fellow, and Dr. Darrel J. Weber, both of the University of Houston, discuss chromatograms recorded by their Phoenix Model K-8000C Analyzer.

APPOINTMENTS VACANT

FISHERIES RESEARCH BOARD OF CANADA

MATHEMATICAL STATISTICIAN

$8,654 to $18,200

Applications are invited for the position of Mathematical Statistician with the Freshwater Institute of the Fisheries Research Board of Canada, on the Campus of the University of Manitoba, Winnipeg, Canada

The nearby University Computing Centre has an I B M System/360 Model 65 computer available with 25K storage, four disc and four magnetic tape drives A 400-million byte graphic display unit will be available shortly It is possible that a remote terminal facility in the Freshwater Institute could be available

DUTIES

1 To develop statistical technique and theory for the study of aquatic populations with special reference to fish , to devise sampling procedures for methods of estimating populations and population changes

2 To investigate the use of systems analysis and modern computer techniques as an approach to fisheries problems

3 To guide the development of a data processing service unit within the Institute and to act in liaison between the Institute and the University of Manitoba Computing Centre

4 To provide statistical consultation in connection with the experimental work of the Institute

QUALIFICATIONS

A Ph D or Masters degree in Mathematical Statistics from a university of recognized standing

CLASSIFICATION AND SALARY

The successful candidate will be appointed within the range of Scientist 2 ($8,654 to $11,340), Scientist 3 ($11 752 to $14,560), or Scientist 4 ($15,340 to $18 200), at a salary commensurate with qualifications and experience Promotions to positions carrying higher classifications are open to all employees of the Fisheries Research Board of Canada

Employees of the Fisheries Research Board enjoy the privileges of the Canadian Public Service Superannuation and Surgical-Medical Plan, etc

APPLICATIONS

Applicants should submit a transcript of academic record a list of publications a statement of experience, training and personal history, accompanied by the names and addresses of three persons who may be consulted for letters of recommendation

The appointment will be made as soon after February 15, 1968, as a suitable candidate can be located Applications should refer to Competition No WPG-25 and be addressed to

The Director,
Fisheries Research Board of Canada
Freshwater Institute,
501 University Crescent,
Winnipeg 19, Manitoba (93)

THE MEDICAL RESEARCH COUNCIL have a vacancy for a biologist to work with a group concerned with the causation of tumours in man The work of the laboratory depends on the close integration of the clinical genetic and virological approaches to this problem The successful applicant will work in collaboration with other members of the staff but will also be expected to develop original ideas within the general area of research Experience in cytogenetics would be an advantage but other candidates who are prepared to train in cytogenetics will be considered Applicants should have a first- or second-class honours degree in a biological subject —Applications giving details of age, qualifications and experience should be sent to the Administrative Officer, M R C, Clinical and Population Cytogenetics Research Unit, Western General Hospital, Edinburgh (71)

ROYAL DUTCH/SHELL LABORATORY, AMSTERDAM

TECHNICAL EDITOR

The Royal Dutch/Shell Group require, at their Research Centre in Amsterdam, a Technical Editor for scientific and technical reports and publications

We expect the post to be filled by a science graduate with a good command of English, but candidates with other, equivalent, qualifications will be considered if they have had experience of editing scientific and technical publications The preferred age range is 25 to 35 years

Starting salary will be in line with qualifications and experience There is an attractive pension scheme We will give financial assistance with the removal of household effects to Holland

Travelling and other reasonable expenses will be paid for interviews in London and Amsterdam

Applications, giving full details of qualifications and experience, should be sent to

SHELL INTERNATIONAL PETROLEUM COMPANY LIMITED
Recruitment Division N (PNEL/1)
Shell Centre, London, S E 1

A NEW FOOD RESEARCH UNIT

The Central Laboratories of the Bovril Group to be situated at Alperton W 5, offer opportunities to experienced graduates for objective basic and applied research

The Unit will form a link with academic and research organisations and our own production research in the following fields

MICROBIOLOGY
FOOD ANALYSIS
BIOCHEMISTRY
FOOD SCIENCE AND NUTRITION

Facilities for research and conditions of employment are attractive

Apply in writing to

Group Technologist,
Bovril Limited,
148/166 Old Street,
LONDON E C.1

(135)

GRADUATE IN AGRICULTURAL SCIENCE OR VETERINARY MEDICINE

required by AN FORAS TALUNTAIS (The Agricultural Institute) for its Pig Husbandry Department at Moorepark Research Centre Fermoy Co Cork for research into environmental factors in relation to performance and health of pigs Starting salary up to £2 465 depending on qualifications and experience Marriage and children s allowances payable in addition Non-contributory Pensions Scheme Special arrangements can be made for F S S U members Working conditions are excellent ESSENTIAL Either (a) an Honours University Degree or equivalent in Agricultural Science, or (b) a University Degree or equivalent, in Veterinary Medicine

Application forms and further particulars from the Director, An Foras Taluntais, 33 Merrion Road, Dublin, 4 (telephone 693222). (Quote Ref N) Latest date for receipt of completed forms is February 14, 1968 (154)

drug research

The Research Division of Pfizer Limited is broadly based in the major scientific disciplines and has a staff in excess of 400 Internal promotions together with a widening spectrum of research interests have created a need for new senior members of the scientific staff

Those appointed will work in modern well-equipped laboratories located in Sandwich on the Kent coast A wide choice of residential areas is available, and property is reasonably priced

To enable us to fill these important appointments we are looking for

Ph.D. Chemists

who preferably have some post-doctoral experience in the pharmaceutical industry or in a university who are good organic chemists and who are able to direct the work of others They should also have, or be interested in developing, the ability to understand the work of their biological and biochemical colleagues

B Sc., G.R.I.C. or H.N.C. Chemists

who have experience in the synthesis of organic compounds

B Sc. Pharmacologists

who have several years postgraduate research experience

Information Officer

who has at least an H N C and experience in synthetic organic chemistry A knowledge of information retrieval methods would be especially suitable, but it is not essential

Ph.D. Pharmacologists

with or without post-doctoral experience who are interested in the laboratory assessment of new compounds

Ph.D. Biochemists

who have 1 or 2 years post-doctoral experience, preferably in enzymology intermediary metabolism or nucleic acid biochemistry

INFORMAL INTERVIEWS

Senior members of the scientific staff will be available, without appointment, on

THURSDAY, JANUARY 18, 1968, at ST ERMINE'S HOTEL, CAXTON STREET, LONDON, S.W 1, 10 a.m.–9 p.m.,

to discuss these opportunities If you are not able to call please write to the Personnel Manager, Research Division, Pfizer Limited, Ramsgate Road Sandwich Kent (200)

Pfizer

BIOLOGISTS

G K Bureau has been commissioned by Universities, Medical Schools, Research Centres and Industry to find

Biochemists ; Electron Microscopists , Microbiologists , Pharmacologists , Physiologists , Psychologists , Botanists ; Entomologists , Parasitologists , Immunologists and Virologists,

also

TECHNICIANS OF ALL KINDS

Miss J SKINNER, B Sc.,
G K. Bureau Ltd , 196 Oxford St., W.1
01-636 6858

(6)

UNIVERSITY OF WESTERN ONTARIO

LONDON CANADA

DEPARTMENT OF CHEMISTRY

Applications are invited for admission to programmes leading to the degree of M Sc or Ph D in the principal fields of chemical research The department, housed in a modern building, has a comprehensive range of modern instrumental equipment and the use of advanced computing facilities

Prospective graduate students should have or expect to receive, an honours degree (or equivalent) in chemistry All students accepted will receive annual support of at least $3 300

A booklet containing further details will be sent to all inquirers, who should write, stating their major field of interest, to Dr W C HOWELL (149)

FELLOW IN MEDICAL INSTRUMENTATION

The Cambridge Instrument Company seeks a Physician to assist the growth of the Company in the fields of medical electronics and biomedical instrumentation He will effectively be the sole full-time medical adviser, with responsibilities for surveying the entire field of measuring instruments for use in medicine and for submitting recommendations for new products in the light of the Company's manufacturing and marketing capabilities

This important, full-time post is open to doctors from any of the Commonwealth or English-speaking countries, and preference will be given to those who already command the respect and confidence of leading consultants and specialists in hospitals and universities throughout the world

The appiontment is for a maximum of three years only, since it is expected that the successful candidate will return to full-time medical practice with a view to qualifying for consultant status

Candidates should be under 30 years of age and have first-class postgraduate hospital or research experience and an appreciation of general medical practice A keen interest in medical instrumentation is essential

The successful applicant will be resident in the U K during the term of his appointment and will be expected to travel extensively

SALARY Negotiable around £3,500

Please write in the first instance to The Chairman, Cambridge Instrument Company Limited, 13 Grosvenor Place, London, S W 1

Interviews will be arranged in The United Kingdom and Australia (134)

UNIVERSITY OF LIVERPOOL

Applications are invited for the post of Senior Lecturer (I) or Lecturer (II) in the Department of Histology The initial salary will be within the range £2,835 to £3,180 per annum (I) or £1 470 to £2 855 per annum (II) depending upon qualifications and experience

The Department is housed in modernised quarters and has good facilities for electron microscopy, cytochemistry, tissue culture, etc There are separate undergraduate courses for medical, dental and science students and a short advanced course for students reading in the Physiology Honours school It is hoped to institute a full-time advanced course in the near future

Applications, stating age, qualifications and experience together with the names of three referees, should be received not later than February 7, 1968 by the Registrar, The University, Liverpool, 3, from whom further particulars may be obtained Please quote Ref RV/305/N (29)

CANADA

QUEEN'S UNIVERSITY OF KINGSTON

DEPARTMENT OF GEOLOGICAL SCIENCES

SENIOR TECHNICIAN REQUIRED

To be responsible for operation of a section-preparation laboratory in a large, well-equipped department He and an assistant would prepare thin, polished and polished-thin sections of rocks and ores

Qualifications accepted industrial or technical diploma or several years' experience in a similar capacity in industry or a university

Salary commensurate with qualifications

Apply, giving details of age experience and the names of two referees to Professor J W Ambrose Head Department of Geological Sciences, Queen's University, Kingston, Ontario, Canada (105)

THE IMPERIAL TOBACCO COMPANY

invites applications for the following vacancies in its Research Department at Bristol:

BOTANIST

To undertake studies on the tobacco plant with particular reference to the enzymology and biochemistry of maturation and curing Experience in enzymology or general plant biochemistry together with an interest in plant anatomy and microbiology would be valuable but not essential

BIOCHEMIST

To join a team working on the study of the metabolism of the tobacco plant with particular reference to the curing process and pigment forming reactions.

Applicants should have a good honours degree and preferably some research experience.

Starting Salary not less than £1,200 per annum.

Application forms from
STAFF SECRETARY,
IMPERIAL TOBACCO CO., BRISTOL 3.

(136)

Pharmacologist

Major Pharmaceutical Company with research facilities located in Montreal, Canada, has an attractive career opportunity in Pharmacology

THE JOB

To initiate and/or develop screening and follow-up procedures in animals, in order to discover new types of drugs for treatment of functional and degenerative respiratory disorders in man The ability to provide leadership to a supporting staff of 3-4 is essential

THE MAN

Young man with training in Pharmacology to the Doctorate level Some experience in industry or work under a Post-Doctoral Fellowship in the area of respiratory disorders a real advantage

BENEFITS

Top Canadian salary and growth potential Comprehensive health, life insurance and retirement plan as well as paid passage to Canada

You are invited to explore this opportunity in complete confidence Applications should be made promptly by air mail to

The Director of Research, Merck Frosst Laboratories,
P.O. Box 1005, Montreal 3, Quebec, Canada.

(125)

CONTROL ENGINEERING

Current research problems at Capenhurst—such as electrical machines, arcs and plasmas, distribution systems and equipment, human environment—present a range of control engineering problems and we wish to strengthen the team working in these areas by the appointment of a young ENGINEER (or MATHEMATICIAN) who will work on the design and analysis of control systems **Ref N/90**

NEW MATERIALS

We wish to extend the work on novel electrical motors by a thorough investigation of the design of new materials for such machines These materials will probably have composite properties and an ideal background for this work would combine training and experience in METALLURGY, MATERIALS generally and SEMI-CONDUCTOR work with particular reference to their mechanical and electrical properties **Ref N/91**

For all of the above posts initial salary depending on ability, experience and age, will be within one of the following salary bands £980-£1 675, £1,605-£2 045, £1,825-£2 470 £2 430-£3 025

Please apply, or write for further information, to
D C. Page, Head of Personnel Services,
THE ELECTRICITY COUNCIL RESEARCH CENTRE,
Capenhurst, near Chester,
quoting appropriate reference (2)

UNIVERSITY OF WALES

THE WELSH NATIONAL SCHOOL OF MEDICINE

TENOVUS INSTITUTE FOR CANCER RESEARCH

Graduate or post-doctoral

BIOCHEMIST
or
BIOLOGIST

for group investigating the teratogenic and carcinogenic properties of aso dyes Excellent facilities available in newly established research institute Experience in tissue fractionation and of organ culture techniques desirable but not essential Salary within the range £800 to £1 400

Applications, with names of two referees, to The Academic Registrar 34 Newport Road, Cardiff (175)

UNIVERSITY OF VICTORIA

DEPARTMENT OF CHEMISTRY

Applications are invited for the following positions

(*a*) Two full or associate professorships one in Inorganic Chemistry the other in Organic Chemistry to date from July 1, 1968 Applications together with the names of three referees should arrive not later than February 1, 1968

(*b*) Post-doctoral fellowships

(*c*) Graduate research studentships/teaching assistantships leading to the degrees of M Sc and Ph D

Applications under (*b*) and (*c*) will be considered at any time

Further details of the appointment, and of this rapidly expanding university, may be obtained from

Dr A C Ridditoid
Head Department of Chemistry
University of Victoria
Victoria, B C
Canada (14[illegible])

McMASTER UNIVERSITY

HAMILTON ONTARIO CANADA

Applications are invited for several accredited Pathology residency training appointments in the University group of hospitals

Intending applicants are asked to write for details and application forms to the Chairman Committee on Hospital Training, Department of Pathology, McMaster University, Hamilton Ontario Canada (100)

NATURE Volume 217
JANUARY 20, 1968

What is Gulliver Doing?

THE OECD review of science policy in the United States is an unexpected document quite out of character with earlier attempts at the definition of national policies and even a little at odds with the supposed objectives of these delicate exercises in supra-national inquisitiveness Certainly the four examiners have been more concerned with Europe than with the United States They have been looking across the Atlantic for help and advice about a host of problems—the conditions of the universities, the technology gap and the brain drain One thing which comes out clearly from their report is the strength of what may be described as the European feeling which they share, and what they have to say about European problems is at once perceptive and courageous By contrast, their judgments on the United States are sometimes naive, sometimes superficial and sometimes both It is almost as if the examiners shrank at the beginning of their inquiry from a serious attempt to understand the machinery of science policy in the United States and from a clear identification of the serious strains which are now beginning to emerge, and there are many who will forgive them choosing not to rise to this great and time-consuming challenge Unfortunately, it is less easy to forgive the examiners for not producing a coherent summary of their joint conclusions As it turns out, their separate reflections on the condition of the modern world are interesting enough and sometimes stimulating, but they are shot through with idiosyncrasies and even prejudice Is it perhaps possible that the examiners did not have the time to put their busy heads together for long enough to produce a common report ? Or did they calculate that if they shot four separate arrows at the colossus, the chance of striking some vital target would be increased ? Whatever the reason, the OECD would be well advised, with future teams of examiners, to spend more time knocking heads together and less time producing background reports which are almost too big to be useful

The quality of what the examiners have to say about the administration of science in the United States is well illustrated by what it says—or does not say—about the function of the National Science Foundation The general view is that the NSF is intended to have a marginal existence, seeking to provide support for projects which the mission-oriented agencies neglect The examiners seem, however, to have overlooked the serious dangers of this state of affairs The present trouble is that when funds are scarce in Congress, the mission-oriented agencies shed their responsibilities for research when the NSF is unable to take up the slack In the long run, it is unthinkable that fundamental science in the United States can continue to prosper if the National Science Foundation remains the Cinderella that it is in comparison with the mission-oriented agencies or even the National Institutes of Health M Lefèvre comes closest to this view in saying that if there were an equivalent of the NSF in Europe, he would like to see it act more boldly One of the disappointments of the huge report which the examiners have produced is its failure to suggest ways in which the NSF might evolve into the more effective organization which circumstances require

The OECD examiners do, however, agree on the importance in the United States of the system by means of which universities depend on what are called project grants for the support of scientific research, and there is, of course, some truth in this Unanimity does not, however, imply accuracy, and there is at least room for doubt about the reasons which the different examiners give for believing that project grants give science in the United States some of its special qualities Professor Waddington, for example, considers the practice of awarding research grants to individuals in American universities for the carrying out of specific projects as the mainspring of competitiveness—good and bad—among scientists in the United States But is this really the way the system works ? There is at least a chance that the details of the machinery of how grants are awarded are symptoms and not causes of the character of academic science in the United States In any case, of course, research grants are awarded in large numbers for the support of individual research workers at British universities, in aggregate they account for roughly two-thirds of what is spent on academic research in science and technology and the terms of grant are frequently drawn in the finest detail It is true that research grants in the United States usually enable scientists to staff their laboratories in a condition which is considered to suit their status and that British research grants less frequently include an element of salary, but this is a question of degree and not of principle In reality, it is hard to see what would prevent the Science Research Council in Britain distributing what funds it has to spare with the precision, the ruthlessness and the daring which characterize the grant-giving agencies in the United States If British research councils pursue a different kind of policy, the blame must be levelled not at their constitutions but at the advisory committees which flourish in Britain as in the United States As with government, so with research councils—people get what they deserve

In the United States, competition between different agencies for the privilege of spending money in new and rapidly developing fields is probably a more important influence on the character of academic science than the details of the machinery for spending money as such, which is why it is perceptive of M Lefèvre to emphasize the implications of the American attachment to the federalist way of doing public business There is a splendid illustration of this in the contrast between the way in which American agencies compete with each other on common ground and the way in which British research councils deal with borderline territory either by implicit treaties of non-intervention or by collaboration with each other They may be right in choosing to blunt competition, but they are certainly responsible for doing so

In matters like these, the OECD report makes depressing reading The examiners have seen Gulliver but their view is of parts and not the whole But if they have learned only a little about the giant in the round, the shock of their encounter has taught them a great deal about themselves This is where their report is best

The first and most obvious lesson which the Europeans (or two of them, at least) confess to having learned is that European institutions are inflexible in comparison with the American Both M Lefèvre and Professor Waddington protest vigorously at the way in which Europe keeps young men waiting for old men to retire They are, of course, right M Lefèvre has a perceptive passage about the way in which industrial change is frequently frustrated by the force of habit, and it is, of course, absurd that in the middle of the most severe economic crisis for more than thirty years, the British Government should still be able to entertain proposals for keeping industries in being whose continued existence is not merely a public expense but an impediment to change elsewhere It is the same in the universities, and this is the tub which Professor Waddington has chosen to thump Movement, if ever perceptible, tends to be so ponderous that it is an active discouragement Although enlightened professors now accept that the old hierarchical concept of the university department is an anachronism, heads of departments are still kings—particularly on the mainland One way and another, OECD examiners are probably correct in their suggestions that Europe would profit if European institutions were more ready to accept change, and some of their eloquence on this theme may even help to foster change The difficulty, which the European examiners appear to recognize implicitly, is how to foster change in Europe without losing the peculiar qualities of life in the Old World of which they are plainly fond That would be a report worth writing

In separate ways, the examiners have also tumbled on what may be called the European solution—the view that the only sure remedy for the technology gap, the brain drain and the other symptoms of the imbalance of economic power between the two sides of the Atlantic is more effective European unity M Lefèvre and Professor Waddington have arguments on this perennial subject Although M Lefèvre clearly reflects the Belgian view that the abolition of customs barriers is not the end but only the beginning of the European Economic Community, his warning that there has so far been very little progress with the integration of science policy in Europe is at once forceful and timely For what sense can there be, for example, in arrangements which have persuaded three of the six nations in the EEC to support independent programmes of development in fast reactors, to say nothing of the quite separate programme being followed in the United Kingdom ? However bright the future may be for breeder reactors, there is nothing to suggest to people of discernment that the European market will be able to sustain four quite separate designs for reactors like these And exactly the same is true, of course, of the way in which there is no co-ordinated policy in Europe on the support of research in high energy physics CERN may be the most powerful of all proofs that collaboration can be made to work, but its success has not yet persuaded member nations to sink their national plans in the common pool Elsewhere, the machinery of the administration of funds for research will tend towards duplication and not complementarity, which is why there is great merit in Professor Waddington's proposal that decisions about the allocation of funds for research in Europe should be organized on an international basis even though—to begin with, at any rate—money never crossed national borders This is an entirely sound and practical suggestion, and much more likely to lead to something useful than the other suggestion of Professor Waddington's that a European analogue of the American Committee on Science and Public Policy should be established by agreement among the European academies There is every reason why the grant-giving agencies should pursue this matter urgently

Of the lessons which the European examiners have learned about themselves, in the long run the most important may be the undertone of disaffection from the United States which runs through a good deal of what the separate examiners have to say Even though the most useful suggestions in the report are European issues, Americans would be wise to pay close attention to what the examiners have to say about the relationship between the two sides of the Atlantic, for, in their separate and different ways, the four examiners accurately represent opinions and arguments which are growing in strength in the Old World And who, anyway, can fail to sympathize with M Lefèvre in his complaint that industry in the United States seems always to bring superior resources to bear in competition with whatever innovations seem about to flourish in Europe ? That may be what competition means, but it seems hard and it stimulates not merely the will to compete but resentment as well Professor Waddington's complaint that American scientists are less able to engage in contemplative studies but are at the same time inconsiderate of European achievements is necessarily more subjective This case would be hard to prove, and may well be unfounded But in a sense what matters is not the truth but the appearance of it In the quite short space of three years, there has been a marked change in the relationship between Europe and the United States There have been great political and economic strains, and it is not surprising that these are now beginning to have a perceptible influence on the character of the relationships among scientists and between scientific institutions If this should mean that European nations will seek to bring a halt to phenomena such as the brain drain by making Europe a more interesting and rewarding place, no harm will have been done But there is also a danger that the events of the past three years will permanently sour relationships between Europe and the United States from which everybody has profited enormously in the past half century That is something to worry about

Mr Wilson Trims his Sails

Mr Wilson, it is often said, is not a good hatchet man But there need now be no doubt that he is a dab hand with the scissors For the cuts in Government expenditure which he announced to the House of Commons on January 16 are a masterpiece of scrimping rather than saving, chopping rather than changing, putting off rather than cancelling altogether With two important exceptions—defence policy and the postponement of raising of the school leaving age to 16—it looks as if every sacred cow in sight has had its horns neatly trimmed

The most fundamental changes occur in defence policy, or—putting it more grandly (as the Opposition will)—in Britain's world role The order for fifty United States F 111 aircraft has been cancelled, some aircraft carriers are to be phased out sooner, British forces will leave the Far East and the Persian Gulf by 1971 Cancellation of the F 111 will save a total of £400 million by 1977–78—a figure which takes into account the likely cancellation charges The defence budget for 1969–70, which was to have been £1,970 million, will be £1,860 million (all at 1964 prices) By 1972–73, Mr Wilson said, the budget would be down to between £1,600 and £1,650 million at 1964 prices Civil Defence will be reduced to a "care and maintenance" basis, which will involve the disbandment of the Civil Defence Corps, the Auxiliary Fire Service and the Territorial Army Volunteer Reserve

None of these is a sacred cow But the decision to postpone the raising of the school leaving age to 16, and the imposition of prescription charges—at the rate of 2*s* 6*d* for each prescription—undoubtedly are Outsiders find it impossible to describe, or to understand, the horror with which the left wing of the Labour Party will greet the second of these decisions It is best simply to say that it is an emotional reaction springing from the best motives in the world, but hardened by now into a near-neurosis The re-imposition of the charges will bring in an extra £25 million a year, although there are to be exceptions—the old, the young, the chronic sick, and expectant and nursing mothers

The postponement of the raising of the school leaving age is potentially far more serious This is killing the goose with a vengeance—before it has even had time to give evidence of its capacity to lay eggs—but again it is only a deferment, to 1973, rather than an absolute cut It is a programme which Britain could neither afford to have nor to do without—an agonizing decision which has prompted the resignation of Lord Longford from the Government

Compared with this, the other cuts which education has suffered will feel like flea bites Secondary school children, for example, will no longer get free milk at school, capital expenditure in further education building, the youth services and public libraries will be cut by something like £2 0 million this year, £6 0 million next Universities will also feel the draught—their capital building programmes this year will be reduced to one-sixth of the planned level, a saving of £0·75 million—which will provide the University Grants Committee with a tricky problem For next year, 1969–70, the universities will have to make do with £2 5 million less for capital expenditure, at a time when vice-chancellors are already pining for more

Direct grant grammar schools will also be losers The grant which is paid to them, based on the number of pupils in the school, will be cut by £20 per pupil per year, an overall saving of £1 8 million And students will have to face the most extraordinary cut of all At the moment a committee is at work, deciding the amount by which student grants will be increased to keep up with the rise in the cost of living Whatever the committee decides will be cut by half, presumably on the principle that student living standards are only half expected to stay up with those of the rest of the community The grand total for savings on education amounts to £40 million in 1968–69 and to £59 million in 1969–70

The Ministry of Technology has been less harshly treated, and the Atomic Energy Authority, the greatest escapologist of them all, seems to have done it again The total savings in the ministry will be only £13 million in 1968–69 and £15 million the year after, and none of this will come from the programmes by which the ministry supports industries such as shipbuilding and computers The National Research Development Corporation will also come through unscathed The economies will come by maintaining the level of industrial research and development in Government establishments rather than by increasing it The Atomic Energy Authority and the defence research establishments will, in contrast, actually suffer cuts in the scale of support, although details of the figures are not yet available The ministry explains that this order of priorities has been decided on the principle that the support work for industry must not be allowed to suffer, so that long-term gains are again likely to be sacrificed in the interests of short-term economies.

Other cuts in the package prompt the same feelings. If the achievement of the present Government in house building had been better, it might have been easier to accept the need to reduce the number of houses built in 1969 by 15,000. And the building of roads has an economic importance far beyond its face value; despite this, expenditure on the roads is to be cut by £53 million this year and £69 million next. Happily there are to be no similar reductions in the building of hospitals.

It all makes a depressing catalogue. Only in the Stock Exchange was there enthusiasm for the programme. There was a surge of buying, reflecting a hope that this would be the last crisis measure for a little while at least. Elsewhere there was little but gloom.

Honesty is the Best Policy

The poor beleaguered British Government may yet derive some comfort, in the weeks that lie immediately ahead, from the way in which the Department of Education and Science has at last made public the documents on which it formed a view, some months ago, of the proposal to build a 300 GeV proton accelerator under the administrative umbrella of CERN. It is true, of course, that the Government would have done better still to make a clean breast of things right at the beginning, when people were still on tenterhooks wondering which way the cat would jump. That was the time to have made real friends. But even if, as events have turned out, the cat has not jumped at all, it is more than a historical courtesy to know just what Professor Michael Swann's working group told its masters, the Council for Scientific Policy—and to know who is prepared openly to vote against the proposal (see page 221). The whole issue has thus been endowed with a greater sense of reality than could otherwise have been attained. This will be a useful standby later this year, for, even if the issue of the 300 GeV machine is now quietly buried, it is plainly far from being dead.

That said, there are three important issues raised by the publication of these documents which deserve close study in Britain and in other countries which belong to CERN. The most immediate question is domestic, and concerns the relationship between bodies such as the Council for Scientific Policy and the Science Research Council and their joint masters—the British Government on the one hand and the professional community on the other. Constitutionally, of course, there is no problem to be solved. Membership of the two councils is in the gift of the Secretary of State for Education and Science, who is well placed to lay down conditions of membership. People invited to belong can say no, but it is not realistically within their competence to say that they will only serve if the councils conduct their business in some specified manner. In the hiring and firing of advisory committees, it is usually well understood that the minister has first call on whatever advice there is to be given, and that if he chooses he can keep this to himself. Unfortunately, however, there are a number of good reasons why this system functions badly in the provision of advice about the management of science and technology, not the least of which is that the advice which the scientific advisory councils provide is only worth having if the councils and their minister know that it credibly represents the opinions or the aspirations of the professional community. In some quite real sense, the members of these committees are not just wise birds in their own right but representatives of scientists elsewhere. In the circumstances, they are entitled to and should be given a greater degree of autonomy than most other kinds of advisory committees.

The right to publish is an important part of the respect the British Government owes the Council for Scientific Policy. The documents in the case of the 300 GeV accelerator are a perfect illustration of how everybody would benefit from the straightforward recognition of this principle. So much can be inferred by asking what would have happened if the advice of the two councils on the 300 GeV machine had been published last October, before the need to make some kind of response to the proposals of CERN had become urgent.

The Government would certainly not have been the loser. It has not been much of a believer in synchrotron escalation, even at its most enthusiastic. If the Government makes any clear impression at all on this issue, it is that of a sceptical but indulgent and cautious uncle, ready to give the physicists what they want if they have really set their hearts on a project and especially if there is afterwards some hope that they will have no further demands for money. There is no disgrace in this, for it is hard to see how responsible governments could act differently. But does it not therefore follow that the Government would have gained a more sensitive impression of what the scientific community is after if the sensible reports of the two councils had been published? Indeed, the physicists would also have gained, for, since the final version of the report was prepared four months ago, it has become plain that the original design produced at CERN in June can be substantially improved on. The case for the 300 GeV machine would have been stronger if it had been seen to be more flexible. Even the chemists would have profited from publication, for then there would have been more than rumour to suggest how vigorously they are opposed to the project. But if publication is beneficial for the 300 GeV proposals, surely the same rule should apply to a great many of the issues now having to be settled. The advisory councils should not merely be allowed but compelled to publish their arguments. If doing this should run counter to what the constitution says, then somebody should rechristen the committees.

The second issue is the course which the British Government should pursue towards the CERN proposals. The hiatus which has now arisen stems from devaluation and from the need for a further examination of plans at CERN. It is a welcome respite, but it will not last for ever. The chief conclusion of the documents which have now been published in Britain will most probably still be valid for most of the year ahead. In other words, it will probably be sensible that the British Government should participate. But there are grounds for asking that plans for the new machine should be more open-ended.

Whatever arrangements may now be made, however, they are likely only to be temporary. It is not too soon for governments to be thinking of the next machine. There is no assurance at this stage that reason will persuade all nations with an interest in high energy physics that a thoroughly international version of CERN would be the best solution. If there is a chance that super-conducting magnets or some other technical innovation could contain the cost of building more powerful machines, the United States and the Soviet Union might well elect to go ahead independently. In the circumstances, the greatest need is to ensure the closest co-operation within the members of CERN not merely on the building of big machines but in the less spectacular parts of high energy physics as well.

Hovercraft at Bay

Pegwell Bay, in Kent, is to be the site of a British hoverport. After a year's delay and a second session of public inquiry the Minister of Housing, Mr Anthony Greenwood, has granted planning permission for Hoverlloyd to build their hoverport, which is likely to cost nearly £1 million. Detailed plans of the scheme have also to be passed by the minister, as he is anxious to preserve as much as possible of the wild life of the bay. It has also been stipulated that no development can occur within 20 feet of the upper edge of the cliff, so that the geological features of the cliff will remain accessible. A fixed flight path has been approved for the hovercraft so that disturbance to bird life will be kept to a minimum. Dr Peter Gay, regional officer of the Nature Conservancy, thinks that about a quarter of the bay will be taken over from the birds, which include waders and wildfowl. The bay is an important feeding and resting ground for migrants, and a breeding ground for little terns which are becoming less common elsewhere. The flight path is to pass at least half a mile north of the breeding grounds at Shell Ness.

Hoverlloyd's first SR.N4 is due to be completed in the spring. Extensive sea trials will be required before a licence for operations can be granted by the Board of Trade, but it is hoped that the craft will be ready for service by the end of the year. A second craft should be ready in time for a full cross-Channel service to be operated in the spring of 1969.

Hoverlloyd originally suggested using Ramsgate harbour for their depot, but the entrance was thought to be too narrow for safe manoeuvring, particularly in rough weather. Pegwell Bay was then suggested, as having the best conditions for a hoverport. Planning permission was requested and a public inquiry was opened in January a year ago. The inspector's resulting report recommended that the application be granted, although it was thought the whole question of hovercraft travel should be examined within the context of a national transport policy. Following the announcement that British Rail was planning to run a hovercraft service from inside Dover harbour, the minister decided to reopen the public inquiry, to hear the relative merits of Dover against those of Pegwell Bay. It was found that in bad weather British Rail would be able to use their boats as an alternative service. Hoverlloyd, on the other hand, will operate hovercraft only. They will not be able to make a switch, and will therefore require an open site for their operations. The second inspector's report reinforced the view of the first, and, taking into account the effect of hovercraft on the national economy with particular reference to export potential, the minister has finally granted the required permission.

The new planning Bill, which is at present before Parliament, should prevent delays like this occurring again, as a preliminary inquiry should consider any possible sites. Further alternatives will therefore not arise after the public inquiry has taken place, as has been the case with the hoverport.

Pegwell Bay in Kent; future arrivals will be made by hovercraft.

No Reprieve for Stansted

MODIFICATIONS have now been made to the plans to develop Stansted as London's third airport. But they bring little comfort to those who believe that the airport should not be built at all; the changes provide for a re-alignment of the runways which it is hoped will reduce the noise suffered by those who live near the airport. One result will be that the existing runway at Stansted will not be usable in the long term, and will go out of use in the late seventies. Because of this, and because the new plans need an extra 500 acres of land, the cost of the airport will rise by between £8 and £10 million. Costs are now put at £45 to £50 million in the immediate future, rising to £80 to £90 million by the end of the seventies.

The changes have shifted the direction of the runways rather more towards the north. They will no longer lie in the south-west/north-east direction which makes the best of weather conditions in the area, but the change is said to make only a trivial difference to the problem of crosswinds. As a result of the changes, the Ministry of Housing and Local Government says that the number of people affected seriously by noise has been reduced from 28,600 to 10,500, although the number of houses which fall within the perimeter of the airfield increases slightly under the new plan. It is not yet clear how many runways are to be built at Stansted; while the first one is being built, the existing one will be used. But when the second runway is completed the first will be phased out, and it is possible that another two will be built. Much will depend on the imponderables of air transport—very large aircraft, for example, could have the effect of reducing the need for four runways at Stansted. Vertical take-off transport aircraft are also a distinct possibility in the long term, although it is unreasonable to expect them to influence the first part of the Stansted plan.

Most opponents of the Stansted decision will conclude that this is the end of the struggle. But a group in the City of London has in the last week come forward with an ambitious plan to build an airport at Foulness, in the Thames Estuary. The plan, for which no details have so far been released, originated with a firm of consulting engineers, Bernard L. Clark and Partners. Mr Clark, in collaboration with Sir John Howard, of the construction company John Howard, has put forward the idea. It would provide a combined airport and deep water docks on reclaimed land in the Thames Estuary. If the airport alone were developed, it would cost £45 to £50 million—with the docks, the total cost would be £250 million. So far, nobody is taking the plan very seriously—partly because Sir John Howard is away in Kenya on a business trip, and nobody else at his company is willing to comment—but also because of the great costs involved. Airports are not conspicuous money makers, and it is hard to see how the money could be raised. With the Government committed to Stansted, it is unlikely that it would provide either approval or financial support for the scheme.

New Computer Company

COMPUTER Technology is a new British computer company whose first machine will come off the production line in May. Modular 1, as the company's only model is called, will fill a niche only partly exploited by the large manufacturers and even then, its makers believe, will compete in both price and capability.

Based at Hemel Hempstead and at present employing thirty-five people, Computer Technology was founded two years ago by Mr Ian Barron, who had previously worked with Elliott-Automation. The company says that its machine can be made up from any desired number of compatible modules, each specific for such functions as processing, sorting and transmitting information. Modular 1 is a digital computer with integrated circuitry; its price depends on the number of modules required and can range from £10,000 to £1 million.

The company is financed by both British and international capital. The flexibility of the machine is claimed to be an assurance of a life of at least ten years without further research and development costs. It will be interesting to see how it fares among the Goliaths of the computer industry.

How to Make Engineers

A REPORT on the methods used to introduce secondary school students to engineering in Japan and America has recently been prepared for the Goldsmiths' Company by Mr G. C. Sneed. Mr Sneed's findings are of particular interest because, although in Britain university places in engineering may be too few, they are too many, it would seem, for British students. According to the 1966 report of the University Central Council for Admissions, there were 500 places left vacant in technology and 1,100 in pure science. The lack of interest among students may derive partly from the low social status of the engineer and partly from the lack of suitable instruction in schools.

An attempt to remedy this situation has been made by Mr Sneed of Ealing Grammar School, whose introductory engineering course, attended voluntarily by three-quarters of the science sixth form, has already been successful in encouraging highly able students to take degrees in engineering. Mr Sneed has now visited Japan and the United States to study the methods used there to encourage students towards the study of engineering at university.

In Japan, there is no lack of applicants for university engineering places. The value and national importance of engineers are publicly recognized. Japanese pupils in secondary schools are said also to be exposed for three hours a week to a subject called "industrial arts". The aim is to cover recent developments in Japanese science and technology, to impart some basic technical knowledge and to help children form a mental attitude towards modern life in which technology plays a major part.

Entrance to state universities in Japan is highly competitive, but it at least avoids the degree of specialization demanded by English universities. All students must pass examinations in mathematics, a scientific subject of choice, Japanese language and English language. For students attempting to enter a faculty of engineering, physics and chemistry are compulsory scientific subjects.

The training of science teachers is an important feature of Japanese education. There are now forty centres throughout Japan which are devoted to the training of science teachers. Mr Sneed reports that the centres are well equipped and staffed, and have met with undoubted success since their inception in 1960.

Mr Sneed says that the scale of Japanese education should not be underestimated In 1966 there were 346 four-year universities, of which 111 were operated by the state More than 70 per cent of Japanese children stay on at school until or past the age of 18, and 11 per cent receive a university education. In England, 7 3 per cent of boys and 3·2 per cent of girls go to university, these figures, however, are not of course strictly comparable

In the United States Mr Sneed says he has investigated the Engineering Concepts Curriculum Project (ECCP), a scheme which calls for the development of an introductory course in engineering and the training of teachers to conduct it The aim is not specifically to attract students to a career in engineering but, like the industrial arts course in Japan, to provide an understanding of the technical background of modern life There are signs that the popularity of engineering as a career in the United States is decreasing and, although it is too early yet to evaluate the course developed by the ECCP, its progress will be watched with interest

Education for Engineers

PLANS to bring the United States Commission on Engineering Education into the structure of the National Academy of Engineering were announced in Washington DC last week The commission was founded by the National Science Foundation in 1962 to meet the needs for improving undergraduate education in engineering It is supported by the NSF and by private means Since 1962, the work has covered areas such as the educational aspects of computers, manpower requirements for engineers in specific fields, the development of an Engineering Concepts Curriculum Project for high schools and the development of undergraduate engineering laboratories

The reason for the proposed association is that the commission recognized a need to establish "a more substantial basis of operation than that provided by its independent status" According to Dr Eric A Walker, president of the National Academy of Engineering, it is hoped that this relationship will encourage new ideas and new programmes as well as establishing co-operation with other organizations dealing with engineering education Formal dissolution of the commission as a corporation will take place no later than March 1, 1969 Meanwhile, the commission will continue to administer existing programmes, and new projects will be handled by the Committee on Engineering Education within the academy

Some Steam Ahead

THE award to a British company of a contract for a large turbine generator for Consolidated Edison in New York is a considerable coup at any time To beat General Electric and Westinghouse, and the highly effective Swiss company Brown Boveri, adds savour to the triumph But there must be some long faces in Associated Electrical Industries just the same If the order had come only two months ago, it might have been decisive in turning away the bid with which Mr Arnold Weinstock of the General Electric Company took over AEI Naturally AEI is trying very hard to play down the issue, despite its jubilation at winning the order Mr Weinstock, for his part, must be gratified that the turbine division of his new empire is already giving evidence of its competitiveness—it could mean one less problem for him, and keep alive hopes of maintaining the division through a difficult period The Central Electricity Generating Board is now cutting back so hard on new orders—despite the recent cold spell, it still had substantial spare capacity—that there is little hope of selling generating capacity in Britain for the next two years or so Export orders are therefore more than just an encouragement—they are a lifesaver

The contract which AEI has won is for one turbine generator with auxiliary equipment, worth £10 million, but it is more than likely that an order for another similar unit will be forthcoming Placing contracts in this way is a common practice in the United States, and AEI is confident of winning the option. The generator is of unprecedented size for a British company—1,100 MW from a single shaft, against the 660 MW units which the CEGB has reached The unit will be run from a boiling light water reactor, and will be a relatively low pressure, low temperature unit, running at 1,800 rpm These units are different from the ones the CEGB uses, which use a higher grade steam

Because the steam from the reactor will be saturated with water, and partially decomposed into hydrogen and oxygen, there are particular corrosion and erosion problems on the turbine blades The amount of erosion depends on the tip speed of the turbine blades, so it pays to keep this as low as possible AEI has managed to do this by using a device developed by one of its engineers—the Baumann multi-exhaust Although the other tenders for the Con Ed contract specified a blade size of 52 inches for the final set of blades, AEI says that its blades are much smaller The generator will use a combination of cooling techniques The stator will be water cooled, by a design which AEI itself developed But, although there had been speculation that the rotor would also have to be water cooled on a unit this size, AEI have provided hydrogen cooling This is not because it is technically impossible to cool the rotor with water—AEI is convinced that it knows how to do it—but merely because it might provide a weak link in the design Cooling by hydrogen gas is well proved, so AEI has decided to use it

The set will also be provided with a series of water separators, designed to remove as much water as possible from the steam In the design of these, AEI will be calling on the experience gained in the contract for the turbines for the steam generating heavy water reactor at Winfrith Heath in Dorset Although the SGHWR is very much smaller than the Con Ed contract, it shares some of the problems

The Lunar Society

from D G King-Hele

THE informal but influential meetings of the Lunar Society of Birmingham began about the year 1766, and its 200th anniversary was commemorated in

October 1966 (see *Nature*, **212**, 229, 1966) At Birmingham the bicentenary was celebrated with a fine exhibition at the City Museum and Art Gallery, seen by 90,000 people, and with a series of lectures, which has now been published in the *University of Birmingham Historical Journal* (Vol XI, No 1, pp 1–111; 1967) The texts of the seven lectures are prefaced by the address at the opening of the exhibition, given by the President of the Royal Society Professor Blackett stresses the important role of the Lunar Society in helping to bring about the Industrial Revolution, particularly through the work of Boulton, Watt, Keir and Wedgwood He also draws attention to the "all-importance of the marriage between science, technology and industrial management", so well exemplified by the members of the Lunar Society, and subsequently so sadly neglected in Britain until very recently.

The first of the lectures, on "The Origins and Lifespan of the Lunar Society", was given by Eric Robinson, who also wrote the greater part of the excellent catalogue of the exhibition The Lunar Society originated in the meetings of Erasmus Darwin, William Small and Matthew Boulton which, Mr Robinson concludes, were certainly taking place by 1766, often in Darwin's house at Lichfield. The end of the society, like its beginning, was ill-defined Mr Robinson shows that it survived until about 1807

The next two contributions are devoted to individual members of the society Lord Cohen of Birkenhead gives an interesting account of the life and work of Erasmus Darwin, well illustrated and with a useful bibliography of Darwin's published works This is followed by an appreciation of William Withering by Sir John McMichael, who shows that Withering's use of digitalis in the treatment of dropsy was subtle and far-sighted The next three lecturers discuss the influence of the Lunar Society on the development of chemistry, education and Birmingham Chemistry brings in Priestley, Keir, Watt and Wedgwood in education the chief contributors were Edgeworth and Darwin, and in Birmingham it is Boulton who reigns supreme In the final lecture, "The Lunar Society and the Industrial Revolution", R E Schofield skilfully sums up the contributions of the Lunar Society members in each branch of "industry", including medicine and agriculture, as well as technology in the narrow sense

More Trade

During this week, Academician V A Kirillin, chairman of the State Committee for Science and Technology of the USSR, has been visiting Britain The principal reason for his visit is to sign the technological agreement between the UK and the USSR, which has been negotiated over recent months (see *Nature*, **216**, 1060, 1967) From the British side the agreement will be signed by Mr Anthony Wedgwood Benn, Minister of Technology, and Mr Frederick Mulley, Minister of State at the Foreign Office

Meanwhile, the day before Mr Kirillin's arrival, another agreement between the UK and the USSR was being signed It is called the Anglo-Soviet trade agreement, and covers the import and export of consumer goods The agreement has been in force since 1959, and the most recent signing takes it forward to December 31, 1968 The agreement sets up quotas for the trade of consumer goods—the quotas now stand at £7 4 million for the import of Russian goods into the UK, and £6·7 million for the export of UK goods to the USSR These figures, the Board of Trade says, are 60 per cent larger than those agreed for the previous year They are still remarkably small, but fortunately do not represent the full amount of UK–USSR trade Although all trade is carried on within the agreement, the Board of Trade explains that over 90 per cent of it takes place outside the quotas

The USSR seems to be getting slightly the better of the balance of trade at the moment During 1966, UK imports from the USSR amounted to £125 6 million, while exports were just over £50 million Up to the end of November 1967, the balance was slightly more favourable In the 11 months, UK exports to the USSR were £61 7 million, while imports were down to £107 6 million

The new quotas agreed should offer instrument manufacturers a new chance The USSR authorities have agreed to import from Britain scientific instruments to the value of £1 1 million They are also prepared to import £1·08 million worth of chemicals and £820,000 worth of man-made yarns and fibres But it is clear that the vast majority of UK–USSR trade will continue to take place outside the quotas

Cost of Accidents

At a measurable cost to Britain of £246 million for 1965 alone, road accidents are expensive Mr R F F Dawson, of the Road Research Laboratory, has been making detailed investigations into the costs and has now produced figures which he believes to be more accurate than previous estimates made in 1938 and 1952 For the first time a value has been placed on human life and the prevention of suffering, and these subjective costs have been added to the measurable costs to give a figure which represents the total cost of accidents The figure of £1,020 is put forward by Mr Dawson, for use in economic calculations, as the average cost per accident for all areas This and other conclusions can be found in a report, *The Cost of Road Accidents in Great Britain*, which was published last week (RRL Report L R 79)

Costs of accidents are considered to arise from three sources injury to people, damage to property and from incidental expenses such as police and insurance administration Costs of insurance premiums are not included as these would not decrease even if the number of accidents was reduced Damage to property and incidental expenses are paid for by a diversion of current resources, and are comparatively easy to measure Insurance payments during 1963 put the cost of damage to vehicles and other property at £128 million Estimates of police man-hours spent in coping with accidents were made and the cost to the police for 1963 came out at £4 million Insurance administration costs were set at £20 million Injuries to people are the most difficult factor to evaluate Current costs of medical treatment and long term effects of loss of output can be estimated with a fair degree of certainty, but the additional cost to individuals of serious injury or fatal accidents is a matter for speculation Loss of output in 1963 was set at £34 million, £20 million of which resulted from fatal accidents

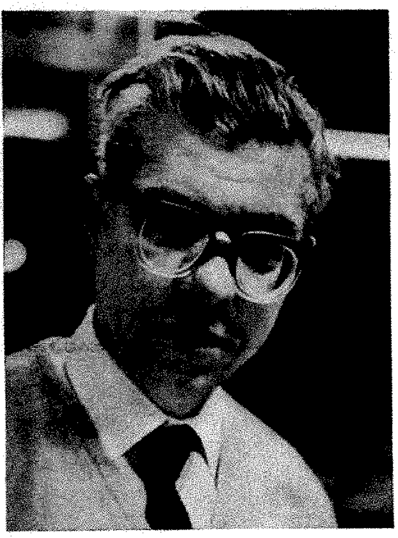
Medical treatment involving hospitals, doctors and ambulances was estimated to cost £10 million. There are no figures available for the costs incurred when vehicles are delayed by accidents and no estimate was included in the final accident costings. Mr Dawson suggested, however, that half an hour's delay per vehicle per year would cost the community £6 million.

The total measurable cost of accidents in 1963 came to £196 million. By 1965 this total had risen to £246 million, and the average measurable cost per accident had risen to £820 from the 1963 figure of £710 for all areas. This particular average is obtained by dividing the total cost of all accidents by the number of accidents in which personal injury occurred. Although this is not necessarily the perfect figure, it makes the best use of the available information. When road improvement schemes are evaluated, for example, public safety is of prime importance, and statistics are compiled with this in mind.

Subjective costs of fatal and serious injuries, which Mr Dawson has introduced for the first time, have been set at £5,000 for a fatality and £200 for a serious injury. In some cases, when a person is supported by the state, their death might result in financial gain to the community. The minimum value that can be put on people's lives is thus the amount of money the community pays to support them. It is on this premise that Mr Dawson made his calculation. When subjective costs are included in the total cost of accidents, the figure for 1965 rises to £306 million, £60 million above the measurable figure. This higher total produces the average cost per accident of £1,020 for all areas. When broken down into categories of road conditions, the estimates put urban accidents at £880, those in rural areas at £1,510, and those on motorways, where higher speeds cause greater damage, at £2,610.

Star Prizes

THE Royal Astronomical Society announced on January 12 the award of its Gold Medal to Professor Fred Hoyle for his contributions to theoretical astrophysics, especially the theory of stellar structure, nucleosynthesis and cosmology.



Professor Fred Hoyle.

Dr W. H. Munk has also received a Gold Medal for his contributions to oceanography and to the study of the variation of the rotation of the Earth.

The Eddington Medal has gone to Drs R. Hanbury-Brown and R. Q. Twiss for their invention and theoretical study of the intensity interferometer. This instrument has now led to accurate measurements of the angular diameters of a series of stars.

The Jackson-Gwilt Medal and Gift has been awarded to Dr J. G. Porter in recognition of his work on the orbits of comets and meteors and of his activities in the promotion of public interest in astronomy.

Fewer Fellows

THE decision reached in November 1967 to reduce the number of Harkness fellowships from sixty-five to twenty has been received in Britain without joy. These fellowships, named after Mr Edward S. Harkness, have enabled deserving young men and women from the countries of Western Europe and from New Zealand and Australia to continue their studies in the United States. The influence of the fellowships has furthermore extended to the growing number of departments in European universities concerned with American studies, where the staff are mainly former fellows.

The value of the fellowship varies, and the Commonwealth Fund in London says that it was difficult to quote an average figure. Despite the fact that the total value of the fellowships amounts to only one-seventh of the Commonwealth Fund—$7,059,190 for 1967—the directors of the fund in New York want to channel more money into medical research, which already receives the lion's share. At least Britain will not suffer quite as much as the other countries and from 1969 onwards will, in fact, be the only country to receive fellowships, with a reduction in the number from thirty to twenty.

There remains the question of where the axe will fall next. The number of fellowships awarded by the National Institutes of Health to United States postgraduates for research in Britain may be the next to be reduced or cut completely.

Sharing out Teachers

ACCORDING to an announcement made by Mr Patrick Gordon Walker on January 18, an improvement is expected in the total supply of school teachers and in their distribution in shortage areas. This week, a circular has been sent by the Department of Education to local education authorities, informing them what their allocation of certain kinds of teachers will be for next autumn. One thing which the circular points out is that some local authorities have been recruiting more than their share of teachers, so that some areas have gone short: authorities are therefore urged to exercise "closer control". The circular also stresses the importance of part-time teachers and of married women returning to teaching.

The fact that definite steps needed to be taken to improve the distribution of teachers was realized in 1956. This led to the introduction of a quota which laid down the total number of teachers to be employed by a local education authority. This quota scheme is confined to schools which are maintained by local education authorities and is a voluntary rationing scheme. It covers the majority of full-time teachers, but not married women returning to teaching after a break in service, and further excludes married women graduates from entering teaching for the first time some years after taking their degree. The purpose of the scheme is to ensure that each local education authority secures a fair share of the total number of teachers available, and the efficacy of the system depends very much on the accuracy of forecasts and the extent to which authorities observe the quota.

The policy of caution adopted in January 1967 was so successful that it is again being adopted for 1968–69. Because of the anticipated increase of 8,000 quota teachers, however, the total number of allocated teachers will naturally be bigger this year. In all, an increase of 10,000 teachers is expected, which will improve the ratio of teachers to pupils over the next few years. The date of operation of the quota is now being fixed for October instead of January, to improve the accuracy of the system.

Medicine Man

The University of Newcastle has appointed as its next vice-chancellor Dr Henry Miller, who is dean of medicine and professor of neurology at the university. There will be widespread pleasure at the appointment of Professor Miller, a cheerful extrovert, to the post. He succeeds Dr C. I. C. Bosanquet, who has been vice-chancellor since the university was constituted in 1963. Dr Bosanquet is retiring because he has reached the age limit for vice-chancellors (65) and Professor Miller, who is 55 this year, will be taking over on October 1.

Professor Miller is best known outside Newcastle for his trenchant criticisms of the National Health Service. He has frequently urged improvements in the standard of hospital care, and is chairman of the British Medical Association Planning Unit. He has held visiting posts in the United States and Canada, and his research work in recent years has been concerned principally with the demyelinating diseases. He is likely to prove an outspoken vice-chancellor, not one of the shy, retiring kind.

Professor Henry Miller.

Controlled Death for Plants

The patient horticulturists who remove the side buds from ornamental plants so that single prize winning blooms will grow may soon find themselves replaced by a man with a chemical spray. This was the impression left by Dr H. M. Cathey of the US Department of Agriculture Research Division, Beltsville, Maryland, when he spoke about what he calls chemical growth assassins to the Society of Chemical Industry at its symposium on plant growth regulators on January 9.

Chemical growth assassins can kill meristems, flowers, anthers or pistils without damaging the rest of the plant. There are three modes of action: hormonal chemicals such as auxin upset the endogenous growth substances; mechanically active chemicals, such as liquid plastic, cover parts of the plant and prevent pollination; and caustic chemicals, which include many aliphatic and aromatic compounds, penetrate and kill restricted parts of plants.

It was on these caustic chemicals that Dr Cathey concentrated. He described how the chrysanthemum cultivar 'Fred Shoesmith', which has between ten and twenty-four lateral buds to be removed for each flower which is allowed to develop, can be chemically disbudded by petroleum fractions containing a large percentage of naphthalenes, indenes, indanes and alkylbenzenes. These are sprayed on to the leaves together with a surfactant, after the plant has been exposed to fourteen eight-hour days. The lateral flower buds die, but the terminal buds are unaffected and flower at the same time as when the lateral buds are removed manually. Other chrysanthemums and other species are less responsive to this treatment than 'Fred Shoesmith'. The lower alkyl esters of the C8 to C12 fatty acids and the C8 to C10 fatty alcohols, however, can be used in aqueous emulsions to kill selectively the terminal meristems without damaging axillary meristems, foliage or stem tissue. Privet is one plant which can be pruned in this way, which, Dr Cathey remarked, will release a great deal of British labour for other tasks when privet hedges no longer have to be pruned by hand.

The selective action of the caustic chemicals depends on the use of a suitable surfactant to act as emulsifier, wetting agent and detergent and to make soluble the epidermal layer. They regulate the penetration of the organic compounds into the plant so that they can exercise their selective effects.

British Surveyors at Work

The Directorate of Overseas Surveys (part of the Ministry of Overseas Development), with headquarters at Tolworth, Surrey, gives aid to developing countries in land survey, air photography, basic mapping and land resource investigation. Some of the day-to-day work and some of the more unusual projects done by British surveyors are described in the annual report of the directorate, just published (HMSO, 10*s*.). The surveyors worked in sixteen countries during the year in conditions ranging from the Kalahari Desert in Botswana to a primary swamp jungle in Sarawak. Hazards encountered included cyclones in the Solomon Islands, a landslide in Dominica and inquisitive hippos in Tanzania.

The directorate's first task is basic survey and mapping, and since it was established in 1946 it has mapped over 1,654,000 square miles of territory, over 220,000 square miles of this have already been remapped This surveying and mapping is a continuing process, first, accurate maps are needed for planning development schemes, then as the plans become reality new and more detailed maps are required during the different stages of development The change from tribal to individual land tenure, together with the rapid urban development in overseas countries, has also led to more demands for large scale mapping, and an increasing proportion of the directorate's mapping activity has been spent on this type of work.

During the year, assistance was given to forty-six countries In 1966–67, 532 new maps were published, compared with 514 in 1965–66 180 of the new maps are at a scale of 1 5,000 or larger In addition, reproduction material of 96 new maps was supplied to overseas governments for local publication The maps are plotted at the headquarters at Tolworth from air photography and the surveyors' work The plots are then sent to the country concerned for completion in the field by the survey department of detail not visible on the photographs and for the addition of names The final maps are then scribed or fair-drawn and most are sent to the Ordnance Survey for printing

An important feature of the year, says the report, has been the continued expansion of the Land Resources Division to enable the directorate to meet the requests for scientific investigations to aid development planning overseas The division worked for sixteen countries and carried out field investigations in six Training attachments for officers from overseas technical departments form an important part of the directorate's aid to developing countries Senior members of the staff are also seconded to overseas governments At headquarters, research into new techniques, equipment and materials for mapping continued to be carried out, and exhaustive field tests were made on the MRA 3 and MRA 101 tellurometers in southern Nigeria

Safety in School

A NEWLY revised version of the pamphlet *Safety at School* has just been published by the Department of Education and Science (HMSO, 9*s*) It replaces a similar pamphlet first published in 1948 and refers in particular to fire precautions and electrical safety The pamphlet says that there are positive and negative sides to safety, the aim of safety precautions should not be to eliminate every possibility of accident but to avoid unnecessary risks so that children can face up confidently and sensibly to those which cannot, or should not, be avoided

Improvements in design have helped to make schools safer and more efficient Serious accidents are, fortunately, comparatively rare Figures for the total number of serious accidents do not appear to be available, though no doubt individual local authorities retain records The chapter on road safety is the most disturbing Road accidents are responsible for half the total of accidental deaths in childhood Between 1961 and 1965, fatal and serious casualties in the 5–19 age group increased by 29 per cent, compared with a rise of 15 per cent for the population as a whole

Schoolchildren seem to be taking to the air in sufficient numbers for the pamphlet to include a new chapter on that subject There is also a new appendix on precautions in the use of electricity, and the chapters dealing with safety in science laboratories and workshops and with safety afloat have been re-written and brought up to date The chapters on safety in science laboratories and workshops could be profitably read by practising scientists and technologists outside schools

How Eskimos Adapt

How have Eskimos become adapted to extremes of climate ? This is a question which an international study undertaken by the United States, Canada, France and Denmark may help to answer The idea for the study arose at a recent conference on circumpolar peoples held at Point Barrow, Alaska, under the sponsorship of the International Biological Programme (IBP) Eskimos are particularly interesting because over the centuries they have migrated considerable distances and have been exposed to extremely hostile conditions The purpose of the study, which will be conducted under the auspices of the IBP, is to measure the way in which genetically similar groups of Eskimos have adapted to the varying environments along the routes of migration to do this, research sites have been situated at points along these routes

Danish and French investigators will investigate Eskimo adaptation at Upernavik in north-eastern Greenland—one of the most distant points in the Eskimo migratory pattern, the US research will be directed in the vicinity of Wainwright, Alaska, while the Canadians will work at Iglook in the North-west Territories—the centre of the circumscribed migration route

The US study was developed by the Human Adaptability Sub-committee of the US National Committee for the IBP and is under the direction of Dr Frederick A Milan of the University of Wisconsin According to Dr Milan, it is hoped that their study at Wainwright will determine the way in which "an Eskimo community on the Arctic coast of Alaska has successfully perpetuated itself under severe climatic conditions with relatively meagre resources" In addition, by studying the patterns and habits of Eskimo life, an insight might be provided into human adaptability and evolution in general Scientists from the Universities of Wisconsin, Chicago, Indiana, Oregon, California at Los Angeles, the State University of New York at Buffalo and the Wisconsin State Laboratory of Hygiene will all participate in the US effort Among the aspects of research will be behaviour, psychology and mental illness, ecology, environmental studies, genetic markers, growth and development, local climate and geography, and population history By co-ordinating the data from each of the four countries, an overall picture of Eskimo migration can be built up

According to the IBP headquarters in London, similar studies are being carried out by the Russians and Scandinavians as part of the large-scale investigation of circumpolar peoples The Finns have already completed some work near the Russian border on the distribution and habits of Lapps and are hoping to extend this work

Scientific Libraries Examined

A recent report from the Library Association urges changes in the organization of libraries in Britain.

LIBRARIES in Britain have attracted considerable attention in recent weeks—the problems of the British Museum have made sure of that The report of a committee of the Library Association on scientific libraries (*Scientific Library Services*, Library Association, 16s) is unlikely to stir up public interest in quite the same way but it is none the less important for that

To quote the report, "Government departments, universities, colleges, research establishments and industries which have readily recognized the need for rapid expansion of their scientific or technological branches have often failed to appreciate the need for the same dynamic policy in their libraries Even where library development of this kind is acknowledged to be necessary, it is hampered by the very great shortage of librarians trained in one or other of the sciences" The report is apparently the first comprehensive attempt to review the problem of British scientific library services as a whole It is a result of a study made by a special independent committee set up by the Library Association in 1964, under the chairmanship of Major-General C Lloyd The committee set out to review the provision of specialist library services not merely for scientists and technologists but for other specialist workers in government departments, public authorities, universities, colleges, research establishments and industry

At the local level, the report says, "there exists among scientists and technologists a large degree of ignorance of the availability of library and information services Many are not even familiar with the services and journals available within their own particular field " The committee is disturbed about this lack of exploitation of the literature which is, or could be, available at local level and at the apathy towards local library and literature information services It complains that people rely too much on specialist services provided by research associations and learned societies which are usually available from only one national centre which is "geographically remote from the majority of members". To correct this situation the committee urges that more specialist library and information workers should be provided at the local level and that the local library authority be given a statutory responsibility for developing suitable services

Wherever possible, university libraries should be incorporated into the national scientific and technical library services One recommendation which should be relatively easy to put into practice is that which would allow members of one library free use of related libraries on a reciprocal basis which would do away with delaying procedures such as written applications and letters of introduction Many public libraries, after all, have introduced inter-availability of tickets

On a national level, the committee makes a comparison of the services provided by the National Lending Library, the Patent Office Library, the new Reference Library for Science and Invention and the National Central Library on the one hand with the services of the large state libraries of the Soviet Union and the All-Union Institute of Scientific and Technical Information (VINITI) on the other The committee adds its plea to all the others made in the past few years, that there should be no more delay in the full operation of the National Reference Library It also recommends that this library should be given the task of developing a National Co-ordinating and Referral Centre to "back up" and co-ordinate the specialized and local centres Aslib's national referral organization, operating through the Aslib Information Department and the Aslib Directory of sources of information, could possibly provide the referral services for this centre This would mean finding room for Aslib on the same site as the National Reference Library—a thought for the Dainton committee

The committee has drawn up a table with its recommendations on the structure of scientific and technical library and information services at local, regional and national levels It believes the aim should be that any organization needing scientific and technical documents and information should be able to satisfy at least half of its needs within its locality (half an hour's travelling each way), eighty per cent within the region (two hours each way), and virtually all its needs within Great Britain Central finance should be made available to enable libraries to provide a more efficient service, and the Department of Education and Science should "treat the co-ordinated development of information services as of national importance and urgency", now that it has wide powers in library matters

It goes without saying that specialist library staff are a necessary adjunct to the provision of efficient scientific and technical library services The committee makes several recommendations, some of which are in fact already receiving attention Soon after its establishment the committee asked the Library Association to devise some means for the formal education and admission to the register of scientists of a "mature" age It was pointed out that of approximately 1,000 scientists engaged in library and information work, only 3 per cent were on the register of chartered librarians, and that it was impossible for most of them to study full-time and so obtain formal qualification Accordingly, the association devised a scheme for mature graduate entrants

One way and another, the report covers a lot of ground, it uncovers many inadequacies of the present situation, although it is doubtful when any of the recommendations will be put into practice Major changes are of course affected by the economic situation, like everything else, and there is also uncertainty about what the Dainton committee will say It is to be noted that the views expressed in the report are those of the Scientific Libraries Committee and not necessarily those of the Library Association The association itself is in the middle of detailing a lengthy memorandum to the Dainton committee

CHEMISTRY—NEW AND RECENT TITLES

Aromatic Rearrangements. By H. J. Shine

Professor of Chemistry, Texas Technological College, Lubbock, Texas

CONTENTS Preface, the acid-catalyzed rearrangements of alkyl-and halogeno-aromatic compounds, the rearrangement of esters and ethers, the rearrangement of N-substituted amino-aromatic compounds, the rearrangement of N-oxides, base-catalysed rearrangements, and rearrangements accompanying nucleophilic substitution, photochemical rearrangements, author index, subject index 130s

Reactions of Transition-metal Complexes. J. P. Candlin, K. A. Taylor and D. T. Thompson

Imperial Chemical Industries, Ltd, Petrochemical and Polymer Laboratory, Runcorn, Cheshire, England

CONTENTS Part I Types of reaction of transition-metal complexes, substitution reactions, combination reactions, redox reactions, Part II Reactivity classes of reagents with transition-metal compounds, hydrocarbon reactions, reactions of organic halogen compounds, reactions of carbon monoxide and isonitriles, reactions of OR^-, OH^-, and CN^-, reactivity of H^-, H_2, and H^+, reactions of inorganic compounds, Part III Preparation of new organic systems, stabilized organic systems, indexes 100s

The Thermal Properties of Transition-Metal Ammine Complexes.

W Wm. Wendlandt and J P. Smith.

W Wm Wendlandt, *University of Houston, Houston, Texas, U S A*, and J P Smith, *Texas Instruments, Inc, Dallas, Texas, U S A*

CONTENTS Preface, introduction, experimental thermoanalytical techniques, hexamminecobalt (III) complexes, pentamminecobalt (III) complexes, miscellaneous cobalt (III) ammine complexes, cobalt (II) ammine complexes, chromium (III) ammine complexes, copper (II) ammine complexes, nickel (II) ammine complexes, cadmium (II) and zinc (II) ammine complexes, platinum (II, IV) and palladium (II, IV) ammine complexes, platinum (II, IV) complexes with organic amines, miscellaneous metal ammine complexes, author index, subject index 100s

The Organic Chemistry of Phosphorus. A. J. Kirby and S. G. Warren

A J Kirby, *University Demonstrator in Organic Chemistry, and Fellow of Gonville and Caius College, Cambridge, Great Britain*, and S G Warren, *University Demonstrator in Organic Chemistry, and Fellow of Trinity College, Cambridge, Great Britain*

CONTENTS Preface, nomenclature, synthetic methods, electronic structure, structure and reactivity, nucleophilic attack by trivalent phosphorus, elimination of trivalent phosphorus, free radical reactions at phosphorus, four-centre rearrangements, reactions not involving a central phosphorus atom, nucleophilic attack on trivalent phosphorus, nucleophilic attack on phosphonium salts and pentacovalent phosphorus compounds, nucleophilic attack on tetrahedral P(V) compounds, phosphorylation, author index, subject index 160s

Countercurrent Separation Processes. H. R. C Pratt

Division of Chemical Engineering, C S I R O, Melbourne, Australia

CONTENTS Preface, introduction and basic concepts, steady state cascade theory, the ideal cascade, steady-state cascade theory square and squared off cascades, distillation, equilibrium processes employing a separating agent, other equilibrium processes, irreversible processes gaseous diffusion, irreversible processes mass and thermal diffusion, other irreversible processes, multi-component separations, the unsteady state, appendix, subject index 190s

Mass Transfer with Chemical Reaction. G. Astarita

Professor of Chemical Engineering at the University of Naples, Italy

CONTENTS Preface, introduction, general mathematical layout, slow-reaction regime, fast-reaction regime, transition from slow to fast reaction, instantaneous-reaction regime, transition from fast to instantaneous reaction, slow reaction in practice, fast reaction in practice, instantaneous reaction in practice, special problems, carbon dioxide absorption in buffer solutions, carbon dioxide absorption in hydroxide solutions, carbon dioxide absorption in amine solutions, hydrogen sulphide chemical absorption, miscellaneous processes, author index, subject index 70s

Academic Press

Hormones in Blood

Edited by C H GRAY and A. L BACHARACH

SECOND EDITION

Volume 1, October 1967, xviii+578 pp, 130s

Volume 2, December 1967, xviii+686 pp, 150s.

Since the publication of the first edition in 1961 great progress has been made in the field of endocrinology The methods of estimating steroid hormones have been improved by the speed and convenience of thin-layer chromatography and the speed and increased sensitivity of gas-liquid chromatography, immunological methods have revolutionized the estimation of polypeptide and protein hormones; new knowledge has come to hand concerning the biosynthesis and metabolism of many of the steroid hormones especially androgens and progesterone In this second edition the contributions have been revised and largely rewritten Where a contributor was prevented from enlarging his own chapter, his work has been taken over by a new author

Such a wealth of knowledge now exists on this subject that the new edition appears in two volumes New chapters deal with glucagon, placental lactogens, hypothalamic releasing factors, aldosterone, renin and angiotensin and parathormone and calcitonin Five new introductory chapters describe new techniques and the section dealing with thyroid and thyroid-stimulating hormones has been expanded into two chapters

Treatise on Collagen

General Editor·
G N RAMACHANDRAN

VOLUME 1

Chemistry of Collagen

Edited by G N RAMACHANDRAN

December 1967, xiv+556 pp, 126s

Volume 1 deals with amino acid composition, amino acid sequence, an account of the molecular structure at the atomic level, properties of soluble collagen and its general structure, the details of the molecular transformations in solution, sub-units and special structural features of tropocollagen and an account of intact collagen as it is obtained in tissues

CONTENTS

J E Eastoe. *Composition of Collagen and Allied Proteins.*
Kurt Hannig and Arnold Nordwig *Amino Acid Sequences in Collagen*
G N Ramachandran *Structure of Collagen at the Molecular Level*
Alan J Hodge· *Structure at the Electron Microscopic Level*
Karl A Piez *Soluble Collagen and the Components Resulting from its Denaturation.*
Peter H von Hippel *Structure and Stabilization of the Collagen Molecule in Solution*
P M Gallop, Olga O Blumenfeld and S Seifter *Subunits and Special Structural Features of Tropocollagen*
Arthur Veis *Intact Collagen*
J P Carver and E R Blout *Polypeptide Models for Collagen*

Echinoderm Biology

Edited by N MILLOTT

SYMPOSIA OF THE ZOOLOGICAL SOCIETY OF LONDON, NUMBER 20

December 1967, xiv+240 pp, 63s

Echinoderms have for long formed a rich hunting ground for the palaeontologist, comparative anatomist and embryologist

CONTENTS

NEWS AND VIEWS

Keepers and Readers

THE report of the Library Association on scientific library services (see previous page) is sensible enough in what it has to say about the organization of a national library network and the training of librarians, but what it has to say about the defects of the scientific literature is at once pedestrian and dangerous. To readers of *Nature* at least, the committee has given the show away with its assertion that among "advance announcement publications ... *Nature* is performing a useful function but it seems that, because of the overwhelming amount of material, lengthy delays are occurring in the announcement of even the briefest outline details". The association agrees that this is erroneous and has kindly undertaken so to inform the readers of its official journal. In fact, the time lag in publication is now only a few weeks and may be even less before the year is out. A part of the trouble seems to have arisen because the association's report has been in draft since 1965, which suggests that the committee's concern about delays in publication should be extended to its own operations.

What the committee implies about the character and quality of the scientific literature is, however, even more alarming. What, for example, is an "advance announcement journal" and what is its function? The committee says there is a need for some means of bridging the gap between "the completion of a report on a scientific task and the ultimate publication of the report", points to the danger that this system may be used as a means of "claiming priority by people who have no serious intention to follow up" and urges that more should be done to "gain speedy publication of full papers"—which is "not to say that there is no place whatever" for "advance announcement publications", among which are singled out *Physical Review Letters* and *Nature*. This is a curiously mistaken view of what rapid journals are for. To begin with, a great many communications in them are complete in themselves, and it would be folly to ask that they should eventually be published somewhere else at even greater length. In practice, the rapid journals have to be as discriminating as the more ponderous journals, if only to avoid being swamped by the demand for space. In the nature of things, referees play an essential part. The difference is that the rapid journals apply or should apply as rigorously as they can the test of whether an article sent for publication really deserves to be published rapidly. *Nature*, by tradition and inclination, is also keen to publish material which does not fall easily into accepted classifications. When the committee of the Library Association writes that public funds should be used to help societies start more rapid publications, it begs more questions than it knows.

The committee also shakes its head in sorrow about the delays which are supposed to occur "because scientists sometimes have to search for journals in which to publish" and goes on to say that if this belief is justifiable "then it appears that the state will have to intervene". If this is more than mere bluster, it can only imply passive acceptance of the Parkinsonian law that the volume of the literature will always grow so as to accommodate what authors choose to write. This in turn amounts to a denial of the central problem in the management of the literature—the devising of techniques by which authors can be helped or even persuaded to write what potential readers are willing and able to digest.

In the circumstances, the committee's proposals for the better management of journals cut very little ice. It is not true to say, as the report does, that nothing can be done to accelerate the refereeing of articles. With many journals, referees are asked not merely to make decisions about the content but to polish manuscripts for publication. Journals could and should employ professional assistance instead. The committee also raises the wrong hares in what it has to say about the mechanical problems of producing journals. It is hard, for example, to believe that "speed is sacrificed for the sake of a high standard of typographical appearance and the sake of retention of advertisers". In practice, electron microscopists are more demanding than any advertisers. In any case, there is no necessary conflict between speed and typographical appearance. In the same way the committee's fondness for "typewriter composition" in the interests of speed can only stem from innocence of the printing trade. Most journals would be slower and also more expensive if they were set in type with typewriters.

The committee of the Library Association is entirely within its rights to raise these questions, for they are interesting and important. It is a pity it has not done a more thorough job.

Protein Group

THE inaugural meeting of the Protein Group of the Chemical Society was held at Burlington House on Friday, January 12. Proteins and nucleic acids are the twin pillars of molecular biology and a forum for the discussion of the chemical aspects of protein structure and its relation to biological activity, a field which draws on disciplines ranging from physics to biology, is greatly needed The proposal to form such a group originated with Dr G T Young, and protein chemists and biochemists are much in his debt for his efforts in launching this new venture The attendance, well over a hundred, at this inaugural meeting, augurs well for the success of the group, which seems likely to do much to speed progress in an important field of research

The six papers read and discussed at this inaugural meeting covered a wide range of topics, X-ray crystallographic studies being the only aspect of current work on proteins not represented The study of conformations in solution by physical methods was represented by a paper, by Dr Haylock and Professor H N Rydon (Exeter University), on the conformation of poly-L-methionine as revealed by n m r spectroscopy at up to 220 MHz, in chloroform–trifluoroacetic acid mixtures the helix breaks down, after protonation of about one peptide group in four, to the unprotonated random coil The tactics and strategy of peptide synthesis were illustrated by Dr Morley (ICI Pharmaceuticals) by reference to the synthesis of a number of physiologically active polypeptides and of a sequence in the neighbourhood of the active centre (the "cleft") of lysozyme The Liverpool group (Dr Agarwal, Professor Kenner, Dr Millington and Dr Sheppard) described a synthesis of canine gastrin and the use of N-methylation to render peptides more volatile and so more amenable to study by mass spectrometry Sequence studies were represented by two papers one, by Dr Butler (MRC Laboratory for Molecular Biology, Cambridge), dealt with the use of maleic anhydride as a lysine blocking agent in degradations with trypsin, the other, by Dr Press (Oxford University), with sequence studies on immunoglobulins, with particular reference to those parts of the molecule concerned in immunological activity Dr Doonan (University College, London) described several interconvertible sub-forms of glutamic–aspartic transaminase and suggested that these were conformational isomerides with identical sequences

It was generally agreed that more inter-disciplinary meetings of this kind were desirable, and a resolution was passed asking the council of the Chemical Society to approve the formation of the group The following were elected to the group committee Professor H N Rydon (Exeter) (chairman), Dr G T Young (Oxford) (secretary and treasurer), Dr M J Crumpton (Mill Hill), Dr R C Sheppard (Liverpool), Professor C A Vernon (London) It is proposed to hold meetings twice a year, the next being at Keele University during the autumn meeting of the Chemical Society in September Membership of the group is not restricted to fellows of the Chemical Society and there is no subscription, those interested in joining should write to Dr G T Young at the Dyson Perrins Laboratory, South Parks Road, Oxford

Phospholipids and Electron Transfer

from a Biochemistry Correspondent

There has been a great deal of progress in the study of the structure and mode of action of enzymes which can be obtained in solution, but enzymes which are bound to membrane systems are at present much less well characterized The membranes are usually complex combinations of protein, lipid and sometimes carbohydrate, and it has proved difficult to disrupt the membrane without losing the activity The phospholipids would seem to be ideal compounds for biological membranes, as they have both lipid-soluble and water-soluble groups in the same molecule Surface active molecules of this type can form structures called micelles in which the lipid groups form a lipid phase separated from the surrounding aqueous medium by the water-soluble groups Recent work on the electron transport systems of microsomes (particles produced by breaking up the endoplasmic reticulum) indicates that some of the enzymes in the microsome depend on the presence of phospholipid micelles of a particular form

The oxidoreductase in microsomes which transfers electrons from reduced nicotinamide adenine dinucleotide (NAD) to cytochrome *c* was discovered by Strittmatter, who showed that the flavin group and cytochrome b_5 act as intermediate electron carriers MacLennan, Tzagaloff and McConnell (*Biochim Biophys Acta*, **131**, 59, 1967) recently described a preparation which was 10 to 15 times more active than the original microsomes which contained much phospholipid as well as flavin, cytochrome b_5 and non-haem iron P. D Jones and S K Wakil (*J Biol Chem*, **242**, 5267; 1967) have now shown that the reactions transferring electrons from the flavin to cytochrome *c* will only take place in the presence of very asymmetrical micelles of phospholipid Extraction of the microsomes with acetone removed 80 per cent of the lipid and reduced the NAD–cytochrome *c* reductase activity to 20 per cent of the original The NADP–cytochrome *c* reductase (which does not use cytochrome b_5) and NAD–ferricyanide reductase activities were not affected The extracted lipids were fractionated, and attempts were made to restore activity by adding the separated lipids to the inactive microsomes Activity was completely restored only when the lecithins and lysolecithins together were made soluble by sonic oscillations. This preparation increased the activity of intact microsomes and, if the lecithin lysolecithin ratio was adjusted, extracted microsomes were restored to much more than the original activity

It has been shown previously that sonic treatment of combinations of lecithin and lysolecithin forms a sol containing mixed micelles which are long helical structures containing much aqueous solvent The synthetic phospholipid γ-oleyl-β-butyryl phosphatidyl choline forms similar micelles and also restores enzyme activity to the extracted microsomes In a note added in proof the authors state that mixed micelles of lecithin and free fatty acids gave the extracted particles twice the enzyme activity of intact microsomes It seems that electron transport from the flavin to cytochrome *c* in this system depends on the presence of lipid material, but the physical form is more important than the chemical constitution

Titrating Proteins

from our Molecular Biology Correspondent

It is nowadays seldom possible to open a journal and not find at least one potentiometric titration curve of a protein, and indeed the behaviour of the ionizing groups and their interactions are matters of considerable interest to the protein chemist and the enzymologist

But it is difficult to disentangle the many individual ionizations which make up the titration curve, and consequently interest has recently focused on spectroscopic methods, whether infrared, ultraviolet or nuclear magnetic resonance, which may be sensitive to the ionization of one type of residue Perlmann, Oplatka and Katchalsky, however (*J Biol Chem* , **242**, 5163, 1967), have now made a new examination of just how much information can be garnered from simple potentiometric acid-base titration curves

They have applied to the data for the protein pepsinogen the analytical procedures previously devised by Katchalsky and his associates for polyampholytes It is known from independent measurements of optical rotation that there is a *p*H-region in which the protein undergoes a change in conformation If the titration curves are plotted in terms of a function known as the buffer-capacity, defined as the *p*H increment for an incremental addition of hydroxyl ions (in effect the slope of the conventional titration curve), one will expect the conformational transition to manifest itself The reason is obvious enough if the protein is pushed into a state favoured by high concentrations of hydroxyl ions, it will respond by ejecting such ions, that is to say there will be a downward shift of certain *p*Ks For a sharp transition, the buffer capacity will then be very high at the transition *p*H, and indeed sharp, relatively spiky maxima are observed The *p*H of the transition—which decreases as the temperature is increased—is given by the position of the maximum, and the area under the curve gives the number of ionizing groups involved The three histidine residues of the protein are evidently implicated in the present case The conformational transition so measured corresponds with that observed in the *p*H-dependence of the optical rotation It is demonstrated further that the temperature dependence of the buffer-capacity curves leads to a value for the enthalpy of the transition, which can here be equated with the heat of denaturation It has, of course, long been clear that titration curves contain such information, but the directness and economy of the methods by which it has been extracted are to be admired

An interesting *p*H effect in proteins has been described by Shinitzky and Goldman (*Europ J Biochem* , **3**, 139, 1967) Earlier work by Shinitzky, Katchalski and others has shown that charge-transfer complexes are formed in aqueous solution between tryptophan and the protonated imidazole ring of histidine One consequence of this association is the quenching of the ultraviolet fluorescence of the tryptophan When the imidazole ring is titrated, the capacity for charge-transfer interaction is lost and the tryptophan fluorescence is restored Shinitzky and Goldman have now shown that the existence of these associations is surprisingly widespread It occurs in small peptides of histidine and tryptophan, but also in a large number of proteins, as judged by increasing fluorescence with rising *p*H in the neutral range In nearly all cases the fluorometric titration gives an apparent *p*K between 6 and 7, which renders the involvement of histidine highly likely—though other charged groups can also quench Given this measure of uncertainty, the method offers the possibility of determining ionization states of strategic histidines Whether these charge-transfer complexes are functionally significant remains an unanswered question

Nitrogen Fixation

from our Microbiology Correspondent

IN 1966 it was found that the nitrogen fixing complex could reduce acetylene to ethylene, a process that might prove important as an index of nitrogen fixation. At the University of Wisconsin, R H Burris (one of the discoverers of acetylene reduction by nitrogenase) and his colleagues have applied the method to the estimation of nitrogen fixation in the field (Stewart, Fitzgerald and Burris, *Proc US Nat Acad Sci* , **58**, 2071, 1967) Their success is a great stimulus to ecological studies of nitrogen fixation since the existing analytical procedures, based on changes in total nitrogen or nitrogen-15 assimilation, lack sensitivity or are expensive in time and equipment Although studies with cell-free extracts have shown that acetylene reduction is catalysed by the nitrogen fixing complex, it is perhaps unwise to rely entirely on this secondary standard; the authors urge that critical studies be verified by the nitrogen-15 fixing method The acetylene reduction assay has overriding advantages, however relative cheapness of materials and measuring equipment, and a sensitivity that makes possible short incubation times and assay of short term changes in the ecosystem. Another technological benefit here is the fact that the nitrogen fixing system has a higher affinity for acetylene than for nitrogen at comparable partial pressures This means that air contamination is not as serious in the acetylene assay as in the nitrogen-15 method and consequently rather simpler apparatus can be used

Stewart *et al* have used the acetylene reduction method to determine nitrogen fixing capacities of lake waters, soils and nodulated plants Thus, diurnal fluctuations in the acetylene reduction of lake waters were followed conveniently and shown to be related directly to the abundance of the blue-green alga *Gloeotrichia* Similarly, day to day variations reflecting the development and disperal of algal blooms could be determined by the acetylene assay The relative ease of the assay also made possible stratigraphical analyses in the lake being studied Reduction rates again were related directly to the abundance of blue-greens of which *Gloeotrichia* dominated the upper 2 metre layer while *Anabaena* appeared to be restricted to deeper water Acetylene reduction by *Alnus*, *Comptonia* and soybean was restricted to their root nodules The data relating to *Comptonia* demonstrated the dependence of not only nitrogen fixation but also acetylene reduction on the availability of photosynthetic products from the higher plant, ethylene production by afternoon sampled nodules was about twice as high as that of nodules sampled in the morning

The correlation between nitrogen fixation and acetylene reduction rates has not been studied extensively so far, but such information is essential if the acetylene reducing assay is to be used to estimate nitrogen fixation *in situ* On the basis of the electron requirements for the reduction of acetylene and nitrogen it might be predicted that the formation of ethylene should proceed three times more quickly than that of ammonia Ratios of 1·59 to 1 25 for the production rates of ethylene to ammonia have been reported for free-living, nitrogen fixing, soil bacteria, but clearly more data are needed to define the variability of this ratio.

Valence and Reactivity

from a Correspondent

An international symposium on valence and reactivity was held in Oxford under the auspices of the Chemical Society on January 9–11. It was attended by nearly 200 members from more than 20 different countries.

Valence problems in the second half of the periodic table (Groups IV–VII) are bound up essentially with the role of *d* electrons. As early as 1931, Pauling had proposed sp^3d^2 hybridization to account for the octahedral shape of SF_6. Further, the existence of complex ions such as ClO_4^- and the non-existence of FO_4^- are argued as evidence that the lower-lying 3*d* orbitals of Cl can be used more readily than the less accessible 3*d* orbitals of F. Similar situations occur when reactivity is considered. Thus, as Professor R F Hudson of the University of Kent showed, some substitution reactions can occur around a silicon atom by a form of ring-closure which does not occur in corresponding carbon compounds, an explanation is possible in terms of *d*-orbital participation in Si.

But the really important question is are we forced to invoke *d* orbitals in these situations, or are there alternative explanations? A careful study of several types of microwave experiments by Dr E A C Lucken of Geneva showed that in many cases alternative explanations were possible.

Some situations, however, did seem to be fairly certain. Thus Professor E H Wiebenga of Groningen showed that a complete account of the polyhalogen molecules and ions (such as BrF_3, I_3^-) can be provided without any use of *d* orbitals, all that is needed is the concept of three-centre bonds and *p* electrons. This definite situation has to be balanced by the equally convincing arguments of Professor N L Paddock of British Columbia, whose account of the phosphonitrilic ring systems such as the chlorides $(PCl_2N)_n$ invokes *d* orbitals in no fewer than two planes.

A reconciliation of these views is possible, as was shown by Professor C A Coulson of Oxford, if we say that $d\sigma$ bonding is seldom important in ground states of molecules, but $d\pi$ is much more likely to be important. Nevertheless in certain excited states, as Professor H H Jaffé of Cincinnati pointed out, a study of ultraviolet spectra shows $d\sigma$ and $d\pi$ orbitals to be necessary.

But the size of these *d* orbitals is critical. They must not be too large, as they are calculated to be for an isolated atom, or their overlap will be small and their contribution to the bonding negligible. Professors D W J Cruickshank of Manchester and C Zauli of Bologna have calculated that both the presence of ligand groups around a central atom, and the mutual spin coupling arrangements of the valence electrons, can provide a mechanism for contracting the size of a *d* orbital. So also can the presence of a formal positive charge on the central nucleus. In this way there is a nice explanation for the greater likelihood of large valence numbers when highly electronegative ligands such as fluorine are used.

An important feature of this symposium was the all-round character of the discussion. Topics of this kind require a comprehensive view. In this case it was abundantly justified.

Discussing Nucleotides

from a Correspondent

Although bad weather cut down the attendance at the inaugural meeting of the nucleotide discussion group of the Chemical Society held on January 9 in the Chemistry Department of the University of Birmingham, the programme was followed mainly as planned. Professor M Stacey formally opened the meeting by welcoming the visitors and Dr A S Jones took the chair.

The first proceedings took the form of a business meeting to constitute formally the nucleotide group. Dr Jones reported that more than seventy people had expressed an interest in the formation of the group and that a provisional committee had met to make proposals about rules and the constitution. The object is "to encourage the discussion of the chemistry including the biological chemistry of nucleosides, nucleotides and nucleic acids". The committee will consist of a chairman, secretary-treasurer and four members who would normally serve for three years. The following were elected chairman, Dr A S Jones (Birmingham), secretary-treasurer, Dr D W Hutchinson (Warwick), committee members, Dr M G Blackburn (Sheffield), Dr D. M Brown (Cambridge), Professor K Burton (Newcastle) and Dr R T Walker (Birmingham). The committee is to arrange a meeting at some convenient time during the early summer.

The inaugural lecture at Birmingham was delivered by Professor Lord Todd, who drew attention to the large amount of work carried out on the synthesis of nucleotide analogues and suggested reasons for their relatively poor chemotherapeutic properties. He indicated that more information is needed about the role of rare bases in nucleic acids and that better methods of forming phospho-diester linkages in oligonucleotides are also required. Among the methods used to determine nucleotide sequence, he suggested that procedures by which one base might be rendered visible in electron micrographs by the use of a specific chemical marker would be worth developing. On the biochemical side he suggested that further work is necessary in order to establish more about the nature of the infectivity of viruses in particular to decide why some RNAs are infective while others are not.

There were also four contributed papers. Professor K Burton (Newcastle upon Tyne) gave some results on the effect of specific chemical reagents on the acceptor activity of transfer RNA and pointed to the need for a method of determining the tertiary structure of transfer RNA. Dr T L V Ulbricht (Twyford Laboratories) discussed the use of optical rotatory dispersion in the determination of the conformation of nucleosides and its application in the determination of the conformation of nucleic acids. Dr G Shaw (Bradford) discussed investigations of the chemical reactions involved in the biosynthesis of purine nucleosides, in particular the carboxylation and decarboxylation of some substituted imidazoles. Dr A S Jones (Birmingham) described the synthesis of polymeric analogues of polynucleotides, including polyacrylate derivatives with purine and pyrimidine side chains, and polycarboxymethylthymidine. These polymers interact in solution with polynucleotides.

The British View on the Big Machine

Should Britain support the plan to build a 300 GeV proton accelerator somewhere in Europe? A document just published shows that not everybody thinks it should

THE Department of Education and Science has now published the documents which have helped to form the policy of the British Government on the construction of the 300 GeV proton accelerator (HMSO, 7*s* 9*d*) At the last Council meeting of CERN on December 13, 1967, a final decision about the machine was postponed at least until March and probably until the end of 1968, partly so as to allow Britain and Spain to assess the implications of devaluation for their membership of CERN, but chiefly because there is a feeling—fostered by the Government of the Federal German Republic—that there may be profit in reconsidering the technical design of the 300 GeV machine put forward last year by the European Committee for Future Accelerators The publication of British documents, the chief items of which are opinions of the sub-committee of the Council for Scientific Policy under Professor Michael Swann, and of the Science Research Council, is of some importance because the Department of Education and Science was at first inclined to keep this material to itself

Devaluation

In his introduction to the report, Mr Patrick Gordon Walker, Secretary of State at the Department of Education and Science, says that the decision about the 300 GeV machine "cannot be considered by itself", but must rather be "part of the plan for all high energy physics, both national and international" Mr Gordon Walker also points out that the opinions which have guided the formation of policy on the 300 GeV machine were given before the devaluation of sterling The reduction of the external value of the pound will increase the direct cost of participation but not necessarily by the full amount of the devaluation because, "if the United Kingdom were to participate, its share of the cost of the project would in due course be re-assessed" Devaluation may also change earlier views about the advantages of siting the project in Britain, and has already made necessary a reconsideration of the British Government's involvement in projects overseas "The Government will announce its decision in due course"

Listed in the report are the members of the working group appointed by the Council for Scientific Policy Chaired by Professor Swann and working in close collaboration with the Science Research Council and its Nuclear Physics Board, the group was formed to examine the implications of the proposed accelerator and to assess the wider effects of implementing it The group includes Dr J B Adams, UKAEA, Dr F S Dainton, vice-chancellor of the University of Nottingham, Professor B H Flowers, chairman of the Science Research Council, Dr J C Kendrew, deputy chairman of the Medical Research Council Laboratory for Molecular Biology, Cambridge, and Professor A B Pippard, professor of physics at the University of Cambridge

In a letter to Mr Patrick Gordon Walker which is included in the report, Sir H S W Massey, chairman of the Council for Scientific Policy, states that he and his council members share the view of the SRC "on the scientific value of the 300 GeV project and on the importance for European basic science" It should be possible, he adds, to accommodate the project within a budget for nuclear physics rising at seven per cent a year for the next decade, but that it would be more than this in the early 1970s Should costs rise, however, he suggests that they should be met by savings from the budget for nuclear physics Sir Harrie also points out that the benefits to Britain of having the machine in Britain would be great despite the diversion of resources which would be necessary to establish and maintain it

Escalation

The council takes the line that an escalation of cost in building and operating the 300 GeV machine could seriously divert resources from the rest of science and that the project should not be undertaken without assurances that this will not happen (Lord Jackson, one of the fourteen members of the committee, is described as "having reservations about the practicability of achieving such safeguards") The council also emphasizes that long-term planning on behalf of nuclear physics will put the rest of science at a disadvantage unless there are long-term plans to foster developments elsewhere

According to the working group, it is essential for Britain to participate in the project if it is to continue with a high energy nuclear physics programme Reference is made to the possibility of a substitute for the 300 GeV machine, such as obtaining access to the 200 GeV machine in the United States Workers from the US would in return have access to the Intersecting Storage Rings (ISR) facility at CERN Such a scheme would obviously depend on assurance of access to a substantial proportion of the machine time—which is unlikely Another hazard which the group visualizes is that the cost of mounting experiments at such a great distance would be excessive There is also the danger of generating a further brain drain For these reasons, such a substitute would therefore be a poor one

Work at this level is of course expensive and there is no guarantee that it would have commercial applications If Britain were to participate, it would have to be recognized that the country would be committed for the next thirty years The group therefore considers that even on present price estimates, the project could only be financed if science resources rose at an annual average of about nine per cent for the next decade

Cost

The actual cost of the project falls into several parts the cost of constructing the machine together with ancillary costs which must be met by the host country, operational and experimental costs, the cost of necessary national facilities, and the necessary supporting costs for research staff in British universities to enable them to use the machine Assuming that Britain would contribute 25 per cent of the cost, its annual contribution would be as shown in Table 1 The host country would be responsible for providing houses, roads, hospitals and schools, while the machine construction, operation and experimental costs would be shared among nations according to their gross national product

Table 1. BRITISH CONTRIBUTION TO THE 300 GeV ACCELERATOR (£m = 12 m Swiss francs)

Construction phase	Machine proper	General laboratory facilities and services	Preparation for research	Operation of accelerator and experiments	Experimental equipment and facilities	Total £m (rounded)
1967	0 073	0 021	—	—	—	0 094
1968	0 156	0 042	—	—	—	0 198
1969	0 364	0 104	—	—	—	0 469
1970	1 260	0 573	0 104	—	—	1 938
1971	3 573	0 958	0 354	—	—	4 885
1972	3 833	1 115	0 521	—	—	5 469
1973	3 698	1 083	0 833	—	—	5 615
1974	2 969	1 635	1 510	—	—	6 115
1975	1 938	1 750	2 406	—	—	6 094
1976	1 532	1 708	2 885	—	—	6 125

The group acknowledges that the need to insure against the possibility of cost escalation is very real and therefore recommends that Britain should enter the project, but with some reservations First, there should be an assurance that science resources would be allowed to rise at a rate sufficient to allow the rest of science to develop properly Second, there should be a limitation of the construction and operation costs of the machine and ancillary equipment by previous international agreement Third, commitment on operation and equipment costs should be deferred until construction costs are clearly defined Finally, any increase in costs during the construction phase should be met by corresponding economies in the nuclear physics budget. Even if these safeguards were observed, the group suggests that Britain could only just afford to participate in the project and maintains that, if ever another machine were proposed, it would have to be built on a wider basis than that of collaboration within Europe

The working group's report also refers to the SRC's Forward Look for 1968–69 to 1972–73, in which the SRC demonstrates how the costs of the project could be maintained within the amount provisionally allocated to it by the CSP for 1968–69 and 1969–70, provided that the SRC received some of the CSP unallocated reserve Already, Britain's expenditure on nuclear physics research is more than £17 million a year, and if participation were agreed to, this would rise to £34 2 million by 1977–78—an annual rate of increase of seven per cent from beginning to end of the period The ECFA, which made a detailed design of the machine and an estimate of cost, did, however, state that the proposed equipment for the machine is at a level "entirely appropriate to the general scale and importance of the proposed accelerator" and that it is "far from extravagant"

If the figure of seven per cent were to be insufficient to support operation and growth of the 300 GeV accelerator and the CERN facilities, respectively, the group emphasizes that it might be necessary for Britain to withdraw from CERN (Meyrin)

Manpower requirements for the machine should be met without great difficulty, although it might not be possible to accommodate all the extra postgraduate staff required in university posts For this reason, the group states that the SRC should award essentially temporary postdoctoral fellowships at the universities so as to transfer acquired skills into industry As for the benefits, the group recognizes that although the project would be of extreme scientific interest and the results would be important, there are, on the other hand, many scientific activities of comparable interest which cost only a fraction of the amount required to finance the 300 GeV accelerator The project would, it is argued, introduce new dimensions into teaching physics and it would also encourage the flow of technical skills into industry as well as set a challenge to industry as new products and techniques will have to be developed There are also the general political benefits of participating in a European project

Economics

On the economic benefits of participation, Professor Wolfe and Professor Youngson of Edinburgh University maintain that there would be no overall benefit in having the machine sited in Britain The group therefore considers that, on balance, it is not worth offering an extra subscription so as to secure a site in Britain Indeed, there might be a loss incurred if the accelerator were sited in Britain, as the site which has been proposed—Mundford in Norfolk—is one in which there is full employment Drs Wolfe and Youngson furthermore have estimated that if the project were to absorb unemployed resources so that the project would lead to a total net addition to the national product, this would have an adverse effect on the Government stabilization policy, causing wages and prices to rise Overall, their view is pessimistic

This gloomy economic assessment will come as a surprise not merely to those in Britain who have taken it as axiomatic that local construction could not fail to be profitable but also to nations elsewhere in Europe which have been angling for an invitation to build To begin with, Professors Wolfe and Youngson say that they do not believe construction would be completed for £148 million even though they have used this figure in their calculations They also point out that the proposed British site at Mundford does not qualify, under the British legislation on the encouragement of projects in development areas, for subsidies which would amount to something like £6 million spread over the period of construction

The calculation in the report suggests that the external balance of payments of the United Kingdom would benefit to the tune of between £84 and £136 million during the 30 years which are likely to be occupied in construction and operation of the accelerator These comparatively modest sums are the figures obtained by setting off against the receipts of non-British currency to be expected the costs of imported equipment, remittances by foreign staffs and British tax refunds The direct cost of having the accelerator on a British site turns out to be substantially greater than this According to the calculations implicit in the report, the total cost of providing the land-access and service roads and utility supplies would work out at between £186 million and £336 million according to the extent to which resources would have to be diverted from other projects One way and another, the authors of this study conclude, there would be no significant advantage in building the 300 GeV accelerator in the United Kingdom Professors Wolfe and Youngson suggest that there is no reason to expect that the siting of the machine in Britain would substantially increase the effectiveness with which British companies tender for contracts with CERN

The chairman of the SRC at the time, Sir Harry Melville, also comments on the case for participation in the proposed 300 GeV accelerator Generally, the SRC supports the scientific case for building the accelerator and believes that the estimates of construction and running costs are reasonable The council recommended participation if certain safeguards are observed It thus supports previous views that, despite the importance of the project, it should not be allowed to imperil the development of other disciplines Another safeguard is that other countries should agree to participate on a sufficient scale, and finally that the CERN Convention which is now being negotiated should be revised to ensure adequate safeguards of the rights of participants in the 300 GeV laboratory

In considering the resources which would be required in the five years 1973–74 to 1977–78, the council has estimated that all the expenditure on nuclear physics in the second five years could be accommodated within a growth rate of some five per cent per annum this, however, makes no provision for unforeseen major projects It makes clear the fact that it would not be prepared to meet any deficits in the nuclear physics budget arising from escalation on this project, by re-allocation from other disciplines In the event of any such escalation, the council maintains that additional resources would have to be sought or else the nuclear physics programme would have to be reduced during the construction period with serious detriment to the whole programme Furthermore, during the operational period, total or partial withdrawal from CERN (Meyrin) would be necessary

Concerning the proposed UK site at Mundford, Sir Harry describes it in the report as consisting of flat sandy soil overlying chalk, it belongs mostly to the Forestry Commission British experts are at present conducting elaborate loading tests to determine the stability of the strata and these should be finished by August The SRC is also concerned with the cost to Britain of locating the project there, and maintained that this could be greater than assumed It does, however, suggest that some of the additional costs which would be involved might be offset by the "balance of payments advantage flowing to the host nation"

Sir Harry discusses the possibility of collaboration with the US and the USSR where big machines are already built, or are planned A meeting was, in fact, arranged in Vienna in 1964 of the Americans, the Russians and a party of CERN representatives They examined the possibility of a tripartite provision of a single world facility at the 200–300 GeV level As the report makes clear, however, nothing came of this

Dissent

The SRC view emphasizes that, for the project to be successful, it is essential that the four countries, France, Germany, Italy and the UK, which account for 76 per cent of the CERN budget, should participate Although two members of the council—Professor Sir Ewart Jones and Professor Sir Ronald Nyholm—dissented, the council as a whole supports the proposal and is in favour of an early decision

The dissenting case is brief

"We recognize that a good case, on purely scientific grounds, has been made for proceeding with this project But we are also acutely aware that there are other scientific fields which, cultivated and nurtured as nuclear physics has been in recent years, would yield still richer harvests Some of these are of no less scientific interest and have much greater potentialities for benefiting mankind. In several of these fields we are leading the world, we should be able to offer generous support where such ability is demonstrated, but this we cannot afford to do

"Our participation in this project means that for the next ten years the Science Research Council expenditure on a single branch of physics will continue to consume more than 40 per cent of the funds which seem likely to be available Thus the council's intention gradually to reduce the proportion of its resources going to nuclear physics will be completely frustrated We are convinced that to continue to spend such substantial sums in this direction is not in the national interest and that many scientists in this country, if they are properly appraised of the situation, will view the prospect with dismay Can we expect them calmly to accept a slowing down of their activities whilst we go ahead with a huge project which will directly benefit only two or three hundred academic physicists ?

"We cannot reconcile embarking upon this massive new commitment with our present unsatisfactory and worsening situation Can high energy nuclear physics justly claim to be of such overwhelming merit and importance ? We should urgently be seeking opportunities of investing comparable, and if possible larger, sums in projects which offer some prospect of material advantage to the community and which at the same time serve to train useful scientists and technologists (E R H Jones and R S Nyholm)"

The conclusions and recommendations of the Nuclear Physics Board of the Science Research Council are presented in the final pages of the report. In an introduction the board refers to nuclear or particle physics as one of the main growing points of science, and emphasizes the "outstanding and pressing case for constructing in Europe a 300 GeV proton accelerator" It estimates that the machine would take nine years to build and would serve the needs of European physicists for the next 25 years

The second section of the board's report deals with the present world situation in particle physics and lists the present proton and electron accelerators now in use and the way in which they operate The present position of Britain in the field of particle physics is, it suggests, a favourable one and the scientific and technical skills available indicate that Britain more than any other European country is able to exploit fully a machine such as the proposed 300 GeV accelerator If Britain is to remain an important contributor to this field of research on a world scale, the board argues that participation is essential

A brief description of the machine emphasizes its flexibility It has been designed to produce 10^{13} protons per second and will produce 10–20 GeV beams up to 1,000 times more intense than are at present available Using this machine, not only will the energy range of neutrinos be greatly increased but the time required for a particular experiment will be cut from weeks to days Following the 70 GeV machine in the USSR and the 200 GeV machine in the US, the 300 GeV accelerator would take a natural place in the development of high energy accelerators

Of the 22 sites originally proposed, nine in different countries are still being considered The board refers to the stringent geotechnical requirements of any site, this is because very accurate alignment of the large magnet ring and beam lines is essential and must be maintained in the presence of movable massive radiation shielding and experimental equipment The board holds a more optimistic view of the benefits to any nation of having the machine in its territory Among the benefits the board mentions are easier travelling to and from the site and therefore easier combination of research at the centre with university activities In terms of economic benefits, the host nation would have a near-monopoly of construction contracts, and a proportion of salaries and wages would be spent in that country, to the value of £12 million per annum

One suggestion which has been made concerning organization is that CERN and a new 300 GeV laboratory should both be under a single council, responsible for a single European programme The board recognizes the importance of securing a convention which safeguards the rights and interests of those states participating in the project, and of ensuring that a state could withdraw from CERN (Meyrin) while, remaining in the 300 GeV laboratory and in the general CERN Council

Confrontation in Paris

from our Special Correspondent

A POLICY for science is an elusive thing, not to be pursued by those who hope for quick and easy answers But this seems not to have deterred the members of the Committee for Science Policy of the Organization for Economic Co-operation and Development, who met in Paris last week The committee gathered to hear the last stage in the examination which the OECD has made of the science policy of the United States The meeting was a confrontation between the examiners who have been responsible for the report, and delegates from the United States who know at first hand how science is organized in the United States

The party from the United States was led by Dr Donald Hornig, President Johnson's Special Assistant for Science and Technology He was accompanied by Dr Ivan Bennet, Deputy Director of the Office of Science and Technology, Mr Herman Pollack, Director of International Scientific and Technological Affairs, Department of State, Dr Philip Handler, Chairman of the National Science Board, Congressman George P Miller, Chairman of the Committee of Science and Astronautics of the US Congress, Mr William Carey, Assistant Director, Bureau of the Budget, and Mi James A Shannon, Director of the National Institutes of Health

The report itself falls into two sections The first, prepared by the examiners, consists of four essays written from an individual point of view The second section, prepared by the secretariat, backs up these rather subjective views with some statistical data This is necessary because of the way in which the examiners carried out their survey—a ten day visit to the United States, packed with interviews at every turn, may capture the flavour, but cannot include all the facts The examiners' reports should not therefore be expected be to correct in every particular, nor to agree on every point

The confrontation meeting at the Chateau de la Mouette in Paris covered four broad areas The first, science policy proper, was concerned with the institutions, the problems of defining priorities, the role of Congress, the dangers of the "military-industrial complex", and the integration of science into foreign policy The second area of discussion covered the impact of science policy on academic research One question asked, for example, was whether the efforts being made to produce more qualified manpower could ever be successful Was there not a danger that increasing the output of qualified people would itself have a multiplying effect which would create a demand for more people than could possibly be supplied ? In the third and fourth areas of discussion, science policy and industry, problems such as the distribution of federal expenditure between firms, and the extent to which prosperity in some areas of industrial life relies on federal support, were discussed Professor Casimir raised the problem of the amount of spin-off which derives from large research projects Did one have to have a space programme to get the industrial benefits ? In the US, he said, companies tended to say that the effect of spin-off was negligible, while federal agencies said that the importance of spin-off could not be over-estimated Dr Hornig said that it was hard to reach the truth by polling industry, which tended to oppose large scale federal research and development The identifiable direct spin-off was small, he said, but the indirect effects were considerable

M Pierre Massé went on to discuss the ways in which federally supported science could be brought to bear on social problems Dr Hornig started his reply by saying that there was no problem in finding places for social scientists—lawyers already filled Congress, and economists had an important place in the US And large scale social problems were not as new to the United States as Europeans sometimes implied—there was Social Security and the New Deal in the thirties, for example But one of the difficulties was deciding what should be done—in the cities, for example, half the social scientists thought that the problems could be solved by increasing population density, while the other half thought that it was too high already Technology alone could not solve problems as complicated as this, though it could help Mr Carey added that they were relying heavily on faith and hope in turning to the social scientists—it was not yet clear how they could help, although they were eager to

M Pierre Massé brought the discussion round to the problem of the technology gap The rapid advance of technology had introduced a de-stabilizing effect into international trade relations, and there was a danger that if the US economy became too dominating, it would invite repercussions from Europe Did the United States feel that it was part of its duty to make sure that this did not happen ? In the short term, would it not be in the United States interest to support schemes of industrial good-neighbourliness, to enable Europe to catch up ? Dr Hornig thought that schemes of this sort were not really necessary—"the process of catching up is always easier than the process of getting away" Japan was a living example of this Not only were the differences of wage rates a stabilizing influence, but the rapid flow of technological information also tended to even things up Dr Hornig's recipe was that international relations should be stimulated by competition, mitigated by the effects of the transfer of information and by co-operation on some projects

All this was useful discussion, if at times rather imprecisely articulated What did emerge was at least some reassurance to the Europeans—the United States has not achieved its pre-eminence in science and technology by organizing it in a fundamentally more efficient way There are, of course, occasional felicities of organization which could be transplanted with advantage to Europe, although a number of them would require a more united Europe if they were to be applied with any hope of success But if the fact that the United States administration has not hit upon some uniquely happy form of organization is a reassurance to some European governments, it also means that American experience is unlikely to supply any short cuts to success

The short lesson, although the United States witnesses were far too tactful to put it this way, was that Europe should concentrate in putting its own house in order United States success should be seen as a spur to European success, not as a daunting reminder of failure And observers were left with several clear impressions of the way in which Europe could set about the task The principal need, it is probably fair to say, is for far more genuine collaboration in Europe—the formation of European learned societies would be a worthwhile start On the industrial front, the Economic Community should make sure that its organization provides for effective industrial mergers within Europe, instead of making it easy for United States companies to pick off European companies by lightning sorties with cheque book in hand

Does the United States have a Science Policy?

In Paris last Friday the OECD organized a confrontation between the authors of the review of United States science policy which it is to publish a month from now and a number of distinguished American officials. What follows is a summary of the review.

THE underlying tone of the document which the OECD has prepared is one of wonder at the scale on which science and technology are supported in the United States. In many places, this leads quite simply to suggestions—or hints—that the experience of the United States is not directly relevant to the problems of most nations in Europe. The four examiners appointed by the OECD are also somewhat preoccupied by the constitutional differences between the United States and most European nations. The result is that the published review will probably be more valuable to those outside the United States who seek a sensitive explanation of the relationship between the Administration, Congress and the external organizations such as the American universities than by those in the United States who may have been looking to the report for solutions to some of the problems which are now becoming prominent.

The tone of the review is set by the passage in the introduction which says that "by the magnitude of the resources which it deploys, the United States scientific and technical effort is today the most important in the world, and this immense effort, far from taking the form of a unified policy, displays an astounding plurality of methods, institutions and means. We could not begin to think of reviewing all the questions involved or even of going deeply into every aspect of each question. . . ." The four examiners go on to explain that their reports must be regarded as the "opinions of four European experts of very diverse background and culture . . . " and that they have decided that it would be "preferable that each of them should recount certain of his immediate and personal impressions" than that they should attempt to produce "a single comprehensive report". The result is that the review begins with a statement prepared separately by each of the examiners. What then follows is a more detailed survey of institutions and problems which has been prepared by the scientific secretariat of the OECD.

The Belgian View

M. Théo Lefèvre, the Belgian examiner, begins with the flat statement that it is "impossible to speak of a science policy—in the singular—in the United States". He explains that research and development activities have developed "to meet challenges as and when they impinged on the American consciousness", but that programmes in fields such as atomic energy and space exploration have usually been so broadly conceived as to cover the "whole spectrum of the natural sciences". In this process, however, social science and the humanities have been neglected, and M. Lefèvre points out that it was only in 1965 that the Arts and Humanities Foundation was established "as a sort of puny offspring of the National Science Foundation".

In the United States, M. Lefèvre continues, "an ethics has been successfully created of research and development in the service of progress", with the result that research takes on the appearance of a duty. The response of the Federal authorities to a new challenge is to create a new agency which is usually responsible directly to the President. The creation of a centralized ministry of research would run counter to federalist principles, with the result that there is "no question of centralization as we understand it in our European states of Napoleonic mould". Indeed, M. Lefèvre continues, the same "Federalist reflex" leads some agencies to reserve for themselves only responsibility for programming and planning, leaving the execution of policy to industry and the universities. Although the United States has been able to steer clear of the obvious danger of an oligarchy of technocrats, the vertical organization of research and development has led to the emergence of "feudal fiefs which escape the demands of policy". Because these agencies have been able to interpret their mandates widely, M. Lefèvre considers that scientists in the United States have found them to be beneficial. One consequence is that scientists have been able to approach several agencies for support, with the result that there is only a small risk that valuable projects will be neglected for lack of support. From the outside, M. Lefèvre continues, this system has drawbacks such as duplication and its cost sometimes seems "very high".

Of the President's Special Assistant for Science and Technology (now Dr Donald Hornig), M. Lefèvre says that the lack of power of decision does not prevent this official from being the only person to have an overall view of Federal activities in science. As the Special Assistant's personal team has been strengthened over the years, his influence has increased, particularly in the fixing of the budgets of the various agencies.

M. Lefèvre is also impressed with the recent increase of congressional influence on science policy, and he singles out for special attention the setting up within the Library of Congress of a group of congressional advisers. The result has been to "loosen the stranglehold" of the Administration. One happy consequence has been that there may now be a more equitable distribution of federal funds. On the other side of the coin, the way in which pressures on Congress may subordinate national to parochial considerations may lead to a waste of resources.

M. Lefèvre is more perceptive than his fellow examiners about the National Science Foundation. He defines the foundation's function as that of taking over from the military agencies in the field of fundamental research and of balancing the needs of different sectors. "It is no doubt regrettable that the National Science Foundation does not seem to have succeeded fully in all its tasks. A newcomer, with less power than other agencies and no doubt because its directors have not sought to make it assert more power, its support has more often been complementary than propulsive. . . . In the event of the European countries pooling their efforts, they should equip themselves from the outset with a similar instrument but be prepared to display greater boldness."

In M. Lefèvre's view, although federalist principles and the policy of creating agencies have so far yielded good results, this is more by accident than design. Defects which are tolerable in a society of plenty would be unacceptable in a European society with limited resources. M. Lefèvre points out that Americans are beginning to recognize the importance of cost-benefit analysis of research programmes, and have accepted that science must in future be contained within fixed budgets. "The cost of the Viet Nam war can only bring nearer the moment of decision." The difference between the United States and Europe, according to M. Lefèvre, is that American resources are greater, the United States finds it easier to mobilize resources because of political unity (compared with Europe as a whole) and that the United States is able to set national goals for itself and then set out to achieve them. In science policy, European unity is a precondition of success.

On the issue of technological spin-off, M. Lefèvre considers that the electronics, chemical and instrument industries have benefited directly from the scientific and technical programmes supported by the Federal government, but that the chief influence of the large government programmes on the economic life of the United States has been indirect. For one thing, large projects have helped to create a climate in which research is regarded as an economic duty, in which industrialists are "research minded" and willing to take risks. Another indirect spin-off is the development of the multiversity, the growth of the larger universities and the promotion of smaller institutions into the category of the large. M. Lefèvre considers that research contracts have been chiefly responsible for these developments in higher education. A part of the same trend has been the appearance of large numbers of highly qualified executives in American industry, which has served to reinforce the economic prowess of the United States.

M. Lefèvre's view of the United States is not entirely cheerful, however. "Research sectors are neglected which are or seem to be irrelevant to the challenges which are felt—those who devote their lives to such research are stigmatized as "egg-heads". Regions are undeveloped in which there are no universities or industries which fall under the authority of the agencies. Those who cannot stand the pace are destitute, sometimes to an extent which is unimaginable in Europe. They are left to the paternalism of the churches and the charitable institutions, pending the arrival of the 'Great Society', the resources for which are lacking because they are swallowed up by the war in Viet Nam."

This line of argument leads M. Lefèvre to the conclusion that the growth of science and technology is likely to have an important influence on United States politics. The Federal Government's concern for the supply of scientists and technologists has already persuaded the Federal Government to intervene directly (in 1965) in the administration of education, previously the preserve of the states. He considers that problems of air and water pollution, surface transport and even public health campaigns will increase the tendency for the Federal government to intervene in matters which have traditionally been the prerogative of the states. To be sure, the Federal Government will hang back as far as it can. "But is there still room for such a concept in the web of contractual relationships which the Federal Government has spun around itself. . . . Will not the new forms of federalism which are tending to emerge quite simply be forms of transition towards a more centralized state ? The future will teach us whether science and technology do not

The Examining Board at the OECD meeting. Left to right: M. Pierre Massé, President of Electricité de Frnce; Professor C. H. Waddington, of the Institute of Animal Genetics at the University of Edinburgh; Professor H. B. G. Casimir, director of the Philips Laboratories in the Netherlands; M. Théo Lefèvre, former Prime Minister of Belgium; Mr Gerald Bell of OECD; Dr Jacques Spaey, Chairman of the Science Policy Committee of OECD (the last two were not examiners).

determine an irreversible movement of centralization and unification."

M. Lefèvre also sees as a portent the omnipresence of scientific advisers at all levels of the Federal Government. There are, he says, hierarchies of scientific committees which duplicate in their inter-relationships the hierarchical relationships between the agencies themselves. But the scientists on the advisory committees also retain their links with the universities or industry. This system may well be the best way of circulating new ideas, but there is also the danger that the scientific committees will acquire more than their democratic share of influence. "In the extreme case, is there not a danger that a *de facto* power may become gradually and imperceptibly established at the cost of the *de jure* power and that, in the long run, political democracy may be no more than a front ?"

M. Lefèvre is one of those who believes in the technology gap. Indeed, he considers that it can be traced back to the two world wars in the twentieth century, to the "decolonization operations" which have followed the second of them and which have given European nations a more realistic appreciation of the balance of power in the world. But Europeans have the feeling that the United States is now preoccupied with problems elsewhere, as is the Soviet Union. Europe in the larger sense exists, "in a larval state", with no common economic policy as yet and no policy for research and development. "Many people prefer to shine in their canton without troubling themselves about the whole. In any event, how can the whole be grasped so long as walls are erected between research, the management of the economy and the administration of the estate ?" All this can be seen in the universities, which are "ivory towers, First Empire style". In the same way, in European industry and commerce, men arrive "at the seats of power and at the age of retirement about the same date". There is an undeniable gap, but it is a "managerial gap". And "whereas the American concentrates on the future, on risk and on progress, the European seems to opt for safety first and sometimes even for stagnation". Europeans seem not to have heard of what the Americans know from practice, that "in the sphere of research and development, it is the young people who have the experience".

It is plain that M. Lefèvre envies on behalf of Europe the plasticity of American industry. European nations are tempted to keep dying textile and coal industries alive, but the United States is willing to "let the dead bury the dead". He suggests that there should be a more deliberate development of growth industries in which European countries may have an advantage, a combined European policy on research and development, and the judicious exploitation of "American know-how" under licence. But Europe will not be able to make these policies succeed without political unity—indeed, there is a danger that "if the Common Market does not move towards political unity, we would have created circumstances even more convenient for invasion by large American firms".

This view of the reasons for the disequilibrium between Europe and the United States finishes with the declaration that the United States profits from the brain drain, but that there is nothing to be done about it until Europe can offer scientists and technologists conditions for work comparable with those they find in the United States . . . that United States tariff policy widens the gap, as does the tendency of American industry "to launch into production lines where Europe is beginning to give proof of competence" and when "it divides us by favoured partner policy or by offers of technological co-operation to NATO". In the long run, for M. Lefèvre, there is only one way of dealing with the technology gap as he has defined it—"we must unite by means of common policies on both the scientific and the economic planes. This cannot be done without new trans-national institutions".

The British View

Professor C. H. Waddington echoes the opinion that the structure of the mission oriented agencies in the United States is an important determinant of science policy, and emphasizes the way in which the distinction between operational and research agencies is minimized. The fact that the National Institutes of Health are responsible to the Public Health Service, which is also charged with executive responsibilities for public health, contrasts with the way in which, in Britain, the Medical Research Council is responsible to the Department of Education and Science and not to the Ministry of Health. One result is an "extreme plurality" of administrative organizations which "has enormous merits and also a few disadvantages".

The United States Delegation at the OECD meeting. Left to right: Dr Ivan Bennet, Deputy Director, Office of Science and Technology; Mr Herman Pollack, Director, International Scientific and Technological Affairs, Department of State; Dr Philip Handler, Chairman of the National Science Board; Mr George P. Miller, Chairman of the Congress Committee on Science and Astronautics; Dr Donald F. Hornig, Director, Office of Science and Technology; Mr David Beckler, assistant to the Director, Office of Science and Technology; and Mr William Carey, Assistant Director, Bureau of the Budget.

Professor Waddington says that "American scientific leadership" is at present somewhat concerned about the functions which should be performed by research institutes operated directly or indirectly by the Federal Government (and which appear to cost $4,800 million a year). The difficulty is that most of these laboratories belong in some sense or another to mission oriented agencies, but that many of them have been in existence for such a long time that the "system of priorities in force at the time of their foundation" has been materially altered. The system of mission oriented planning would tend to force unwanted laboratories into decline, while encouraging the creation of others intended to meet new needs. Professor Waddington says that discussions are now taking place of ways by means of which a laboratory belonging to one agency may be enabled to put its resources at the service of some other agency, and he suggests that the vital factor is not the administrative arrangements which may be made but the "entrepreneurship of the laboratory director".

Like his fellow examiners, Professor Waddington has clearly been impressed by the importance of what is called the project grant system as a determinant of science policy in the United States. He also considers it to be the origin of several palpable disadvantages, mostly recognizable in the quality of scientific life in the United States.

The essence of the system is that attention is focused on individual items of scientific work rather than on general progress within a broad area—a system which is "in rather sharp distinction to the traditional practice in European universities in which in general the entity on which a judgment of value is passed has been a department covering a considerable field". Professor Waddington says that the American system has the advantage of making it possible rapidly to "encourage excellence wherever it may appear". Young men can obtain support directly, and do not have to apply through the heads of their university departments who, "for a variety of reasons, may not respond as readily as outside bodies would do". Professor Waddington says that this feature of the American system of awarding grants for research is "one of the main features which has enabled American science to advance so rapidly in the last 20 years".

The machinery for awarding project grants is held to be important. Professor Waddington points out that the National Science Foundation uses some 27 advisory committees, each with about 10 people appointed for comparatively short terms of office. The result is a rapid turnover of committee members and the "almost complete prevention of gerontocracy". Because there is direct contact between committee members and scientists seeking grants, it is "less easy for the professor, however wedded to the old ways, to stand in the light of a young man proposing a new idea". By the same test, the system effectively avoids the danger "of activities in particular fields being dominated by a self-perpetuating clique". Professor Waddington says that these dangers have acted and to some extent still act as a "brake on the rapid advance of European science". Even when European nations rely on committees for advice, the numbers of people involved are too small for the advantages of American practice to be replicated, and Professor Waddington goes on to suggest that it would be worthwhile if the panels which are appointed to review project applications in Europe were organized internationally even though their funds would never cross national frontiers.

Professor Waddington is clearly less enamoured of the effects of the American system on individual researchers. Although grant recipients are stimulated to work hard, this is paid for in unpleasant ways. "One hears of many scientists speaking of American science as a rat race and of the summer courses at Woods Hole or the Federation meetings as the slave markets." He adds the qualification that those who lose in these competitions are not bereft of all support, for "in the last few years, at any rate, any reasonably competent worker could be assured of support which would seem quite lavish in European eyes. The battle which rages so fiercely is for high status and extensive opportunities within a scientific community which is genuinely affluent".

This judgment begets a jaundiced view of the tensions within the scientific community in the United States. Professor Waddington says that it is not uncommon to find scientists who are unwilling to disclose at private seminars the results of work they have done until this has "been safely rushed into print". Because careers depend on recognition, priority of publication may have an "unfortunate importance". Although American scientists are scrupulous among themselves in awarding recognition for accomplishments, "this rule does not apply so strongly to non-American scientists" and this has had "a certain bearing on the picture which the world in general, and Europe in particular, has formed of American science". Because of publicity and the grant system, "American science, largely inadvertently, comes to present itself as even more dominant in the world than it really is. It might do no harm for Europe, with its less spontaneously outgoing methods, to take some consciously planned steps to present its image in a more just balance".

The truth is, in any case, that "project grant support makes it more difficult for Americans to find opportunities for the contemplative imaginative thought which is the seed bed for the most radical innovatory concepts". At the highest levels, Professor Waddington says, this may not be easily apparent, although even among Nobel prizewinners, "it may be remarked that quite a number of American Nobel prizewinners have received their awards for discoveries depending on large machines or the organization of large teams of research associates. There are not many of the major scientific institutions which have, in Kuhn's phrase, 'changed the scientific paradigms' . . ." This difference between the United States and Europe is, according to Professor Waddington, more apparent lower down the scientific hierarchy, for young scientists "and those in middle years who are doing quite well but have not yet hit the jackpot find it rather difficult to spend time mulling over a field of science". Professor Waddington considers that the greater opportunities for contemplative science in Europe arise either from the attainment of a stable university position at an early age, the lack of pressure in the system or even the sheer shortage of the equipment necessary for experimental work. He considers that a more constructive method of attaining the same ends would be to increase the opportunities for postdoctoral research.

On the machinery for the formulation of science policy, Professor Waddington says that in the United States the apparatus is outstandingly effective and farsighted in producing programmes for the development of particular broad fields of science, but there has not yet been developed a means by which "scientists can participate fully in directing the progress of science as a whole". Although no country has been successful in the second task, there are—according to Professor Waddington—special problems in the United States.

The machinery for making middle range strategy—the interlocking network of institutions which includes the President's Science Advisory Committee, the Office of Science and Technology (under Dr Donald Hornig), the committees of the National Science Foundation, the National Academy of Sciences and particularly its influential Committee on Science and Public Policy ("far from being a rubber stamp")—all command Professor Waddington's respect. Private organizations such as RAND and the Brookings Institute have a recognized influence, as have the private foundation, but Professor Waddington is a little worried that the foundations, "once wide open to novel suggestions so long as they were good enough", have more recently adopted policies determined by their senior staff and have become "as mission oriented as the governmental agencies" Of all these sources of policy on science and technology, pride of place goes to PSAC and COSPUP, but these are said to depend not only on the energy, judgment and imagination shown by the leaders on the main committees, but "would be impossible without the solid backing from an adequate supporting staff and the participation of a number of scientists and engineers throughout the country" By comparison, the scale of activities in Europe is "pitiful", and Professor Waddington considers once again that it would be sensible if Europe as a whole were to take a leaf out of the American book and try to establish a European analogue of the National Academy of Sciences—National Research Council, presumably by co-operation between European academies

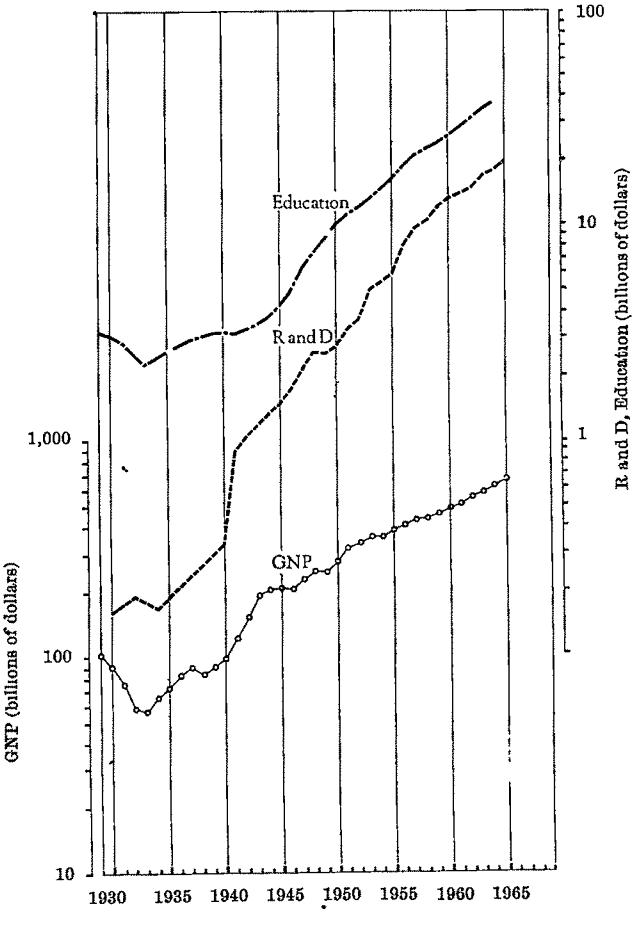
If the machinery for middle range strategy works well, however, Professor Waddington is less happy about the machinery for making decisions on the overall direction of science—questions such as the balance between research and development on the one hand and teaching on the other and the distribution of support between alternative fields of research, both applied and academic He says these problems are ultimately political and that the directions in which a nation emphasizes its support of science must be expressions of political desires and aspirations It follows that Congress must play an important part in the United States It is understandable that the beginnings of science policy in the United States can be traced to the establishment of land grant colleges and the development of agricultural research towards the end of the nineteenth century brought about by the recognition of the need for agricultural development In the same way, the scientific needs of the Second World War have set the scale for Federal expenditure on research and development, which now amounts to $17,000 million a year Since the war, Professor Waddington considers that American society has reacted quickly to the "challenge of ill-health" by the increase of expenditure on medical research, which amounted to $1,900 million in 1965, 64 per cent of it from Federal sources But all these developments are examples of what Professor Waddington calls "subjective programming"—the process of projecting present trends and possibilities into the future He would like there to be more "anticipatory programming", in which people set out first of all to decide what objectives they would like to attain and then seek the means of doing so

Professor Waddington also argues strongly for a greater involvement of scientists in the United States in the social problems thrown up by what he calls "great society science" Simply adding sociologists to existing committees will not help The fact that the social sciences inevitably raise political, ethical and religious questions when they are applied to practical problems impedes the integration of the social sciences into the machinery for making grand strategy Professor Waddington acknowledges that the amount of money spent on social sciences in the United States is quite large compared with what is spent in Europe but he considers there is something to be said for setting up a social science foundation with "a massive Federal grant of capital" and allowing the foundation thereafter "to employ the interest on its capital without further governmental tutelage" Only by such a means will there be any real prospect of applying the techniques of social anthropology within the United States—and even then there is the possibility that "it could not be undertaken satisfactorily by native American scientists, committed by their own upbringing to one of the very systems of social values which would have to be examined"

In education, Professor Waddington is impressed with the success of the Federal Government in bringing about a reform of the curriculum at the high school level He admires the flexibility of undergraduate courses in American universities, and the attempts now being made to improve the "matching of instruction to individual requirements" The emphasis on elective subjects contrasts, Professor Waddington says, with most European systems of university education Those in the Napoleonic tradition are rigidly and centrally prescribed in detail The traditional English system, exemplified by Oxford, requires that a student should follow only one course of studies Among professors at Scottish universities, Professor Waddington must be alone in admitting that the Scottish university system has a few defects, he says that the elective system in the Scottish universities which has been followed for several centuries resembles the American system but that the range of election is much narrower than in the United States

At the undergraduate level, Professor Waddington considers that Europeans have much to learn from the American system For one thing, it is much more able to accommodate advances in knowledge and to find places for interdisciplinary topics But Professor Waddington also considers that the American system provides a more valuable education "as opposed to mere specialist training"

Professor Waddington would also like to see European countries adopting some of the ways of handling graduate instruction now common in American universities Instruction courses for PhD students provide students with help in finding a "way through the mass of relevant information which is so rapidly increasing" Summer schools are in his view splendid innovations and there



Growth of United States expenditure on research and on education as a percentage of the GNP should be encouragement for the attempts being made in several European countries to organize advanced level teaching on a co-operative basis Organizations such as the European Molecular Biology Organization (EMBO), organized unofficially, show that a need exists and this could probably best be met by an international system within Europe which elicited the co-operation of important universities

On the financing of university research, Professor Waddington emphasizes that the project grant system provides flexibility in that it enables new opportunities to be exploited quickly By contrast, "in most European universities, adaptation to a science which is changing radically within small fractions of a working lifetime can only be done if, at the time of the retirement or death of some high-status figure, a professor or head of department, there happens to be a consensus among his surviving colleagues to strike out in a new direction" Apart, however, from its effect on personal relationships between scientists, the project grant system brings administrative headaches in American universities For one thing, it has meant the request by Federal agencies that academic research workers should account in detail for the time spent on various activities The way in which staff members are at liberty to supplement their income by accepting research grants or contracts during the summer is discriminatory against people working in the humanities and the arts, and in any case places the scientists themselves under considerable pressure There is also the problem that the system favours the stronger in his competition with the weaker Professor Waddington discerns the beginnings of a system in which American agencies will award large research grants on an institutional, not a personal, basis The lesson for Europe, he considers, is that there should be a deliberate attempt to "get the best of both worlds" by building up centres of excellence which are closely linked with universities

Like his fellow-examiners, Professor Waddington is impressed with the concentrated power of the very large universities Mass education, he says, is quite out of keeping with the structure and traditions of established European universities One of the problems is how to give young people, while still undergraduates, a sense of contact with experienced men of stature Attempts in the United States to create institutions with a high grade faculty and small numbers of highly selected students, of which "the most extreme example is the Rockefeller University in New York", have found it difficult to maintain excellence in a body which is stationary in size when other institutions are expanding rapidly For the most part, American universities have accepted wholeheartedly the need to become agencies for mass education, and there are those like Dr Clark Kerr who have urged that, under the pressure of public desires for higher education, universities must develop into multiversities More than this, universities are not merely places at which higher education is carried out but social institutions with such a great impact on society at large that "what the railroads did to the second half of the last century, and the automobile to the first half of this century, may be done for the second half of this century by the knowledge industry"

Professor Waddington points out that European universities may be more embarrassed than stimulated by being endowed with such an important part to play For one thing, at present they do not have the money But it does seem to him necessary that some European universities should develop along American lines, both in scale and in influence, and "that Europe should also develop a social system as profoundly influenced by higher education as the American" Indeed, the European need if anything is greater Professor Waddington is particularly concerned that universities should help to predict the ways in which society can change and guide society in moving in these directions He shakes his head a little over the price which the American university system has in his view been required to pay—a lack of unity—and he recommends that there should be attempts to create complexes of universities able to co-ordinate activities Professor Waddington points out that university systems such as the University of California have already gone some way in this direction and that European universities could profitably follow suit

TABLE 1 EDUCATIONAL EXPENDITURE AND GROWTH (1964)

	Education expenditure as percentage of GNP	Growth of education expenditure as percentage of GNP
Germany	3 23	14
France	4 28	50
Italy	4 86	73
Netherlands	5 66	69
United Kingdom	4 49	57
United States	6 18	50

Expenditure at current prices from OECD sources Private expenditure on education not included

On the contribution of American universities to the strength of the American economy, Professor Waddington has very little more to say than that American universities are usually much more closely related to industrial companies than their European counterparts For the most part, in his view, these links are usually beneficial Sometimes industry stimulates interest in pure science More often, academic science gains from the involvement in public affairs The climate in which an interaction like this is possible is also one of which universities and industry have a mutual appreciation for each other's potential contribution One way and another, Professor Waddington concludes, it would not be possible for universities in Europe acting alone to close the "technological gap" by their own efforts, if only because so much change would be required elsewhere in European society and industry.

On the brain drain, he takes the line that nobody has yet done the kind of cost–benefit analysis on which it would be possible to calculate precisely how much European nations lose by the emigration of PhDs On the other hand, there are equally intangible gains to be counted in the equations The pattern he would like to see is one in which European countries encourage young scientists to spend periods of postdoctoral work in other countries but take energetic steps to persuade them to come back again He goes on to say that those concerned with science policy in Europe should take it on themselves to counter-attack the attractions of emigration to the United States by more collaboration between academies in Europe, by collaborative plans between grant-giving research councils and, most promising of all, more collaboration between European scientists as in CERN and EMBO

The Dutch View

Dr H B G Casimir has produced the shortest of all the four examiners' reports and is principally concerned with industrial matters He points, for example, to the scale on which American companies operate and argues that, if European firms are to be able to look their American competitors in the face, they "must operate on an international market"

He points out that at present there is in the United States a "definite tendency against fundamental research" There has been some disappointment with expectations of the benefits of fundamental research which is, in any case, no longer cheap Then putting men on the moon has drained funds away from fundamental science This view, however, is partly offset by the way in which organizations such as the Bell Telephone Laboratories attach great importance to fundamental research carried out in an industrial setting where an "unexpected windfall" is not the chief aim Yet the contribution of industrial research laboratories other than the enlightened handful to the progress of fundamental research has been small

In the progressive industries, on the other hand, companies in the United States appear to do more than their European counterparts to apply scientific methods to the development of existing products and methods.

Dr Casimir is impressed with the way in which it is possible for quite small companies to have access to a large market in the United States without having to equip themselves with an elaborate sales organization. Staff is more mobile, between companies, between universities and industry and between industry and government. Government contracts have also helped to foster technology in the United States even though "we in Europe are inclined to overestimate this influence". Although military contracts have been particularly influential in fostering the development of electronic components of various kinds, it is clear that the influence of the Federal Government has been negligible in the development of motor cars, small in power engineering except for atomic energy and only slight in industries concerned with chemicals, metals and plastics.

To Dr Casimir, the term "technology gap" is inadequate and misleading. As far as industry is concerned "no fundamental science gap can exist". There is, however, a difference in the "scale of operation at the level of technological diffusion". Dr Casimir is all for better management, less complacent industry in Europe and more training in modern business techniques.

The French View

M. Pierre Massé has a more philosophical view of the contrast between the United States and Europe than his three fellow examiners. The starting point for his argument is that the American economy is a dominant force in the world but that science policy is not the prime cause of this state of affairs. In the same way, the "technological gap" is only one aspect of "a whole complex of gaps".

M. Massé shares the view of his colleagues that the way in which the Federal Government contributes two-thirds of the cost of research and development carried out in the United States but spends only one-sixth of the total sum available within its own establishments is a source of flexibility. Whether this great expenditure of federal money does really lead to tangible and valuable "spin-off" is, in M. Massé's view, a controversial point. On the whole, he has the feeling that the economic importance of the big federal programmes is more important than industrialists are usually prepared to admit. One of M. Massé's points is that the techniques of budget control introduced within the Department of Defense and now within the Bureau of the Budget have served as a powerful means of undermining the old assumption that public expenditure is bound to be less efficient than private expenditure so that in the future the American proclivity to decentralize may be diminished. However that may be, M. Massé follows Galbraith (without mentioning him) by pointing out that the growth of large American corporations may have introduced an element of instability into national and international economic equilibrium by eroding "the concealed stabilizer of economic life—the law of diminishing returns". This leads M. Massé to the conclusion, which all his colleagues share, that European unity is the only long-term answer to the technology gap.

Normal Immune Responses of Bursaless Chickens to a Secondary Antigenic Stimulus

by

Houghton, Huntingdon
and
Department of Animal Pathology,
School of Veterinary Medicine,
University of Cambridge

Hormonal bursectomy—inhibition of the development of the bursa by testosterone—has been more effective than surgical bursectomy coupled with irradiation in depressing the primary response to soluble antigens. None of the treated birds was agammaglobulinaemic, and all formed some antibody.

THE failure of bursaless chickens to respond to certain antigenic stimuli (most recently reviewed by Warner[1]) has led to the concept of the "dissociation of immunological responsiveness"[2] which predicates the existence of two populations of immunologically competent cells: one thymus dependent, mediating delayed hypersensitivity reactions and homograft rejection; the other bursa dependent, responsible for specific antibody formation and immunoglobulin synthesis.

The results of experiments showing the absence of immunoglobulins and of specific antibody in bursectomized chickens, however, are not at all straightforward. An unpublished study of ours involving the sera of fifty hormonally bursectomized (HBX) birds and a similar number of controls showed that only half of the treated birds had significantly reduced contents of gamma globulin (that is, ranging from one-third to one-tenth of the normal content) and that of these all had readily detectable gamma globulin, that is, more than 0·1 mg/ml. Large variations in the immunoglobulin contents of HBX birds have been found before[3,4]. In our HBX birds, natural agglutinins to sheep red cells were found 3 weeks later than in the normal controls, but then increased to similar concentrations. Similar results had already been obtained with natural agglutinins to rabbit red cells in surgically bursectomized (SBX) birds[5].

There are recent reports of antibody production by bursaless chickens, either as a result of more than one antigenic stimulus[6] or by detection with a very sensitive test[7]. The presence of antigen in the circulation of BX birds several days after its clearance by normal controls—the best criterion of unresponsiveness—has only been demonstrated in HBX birds after primary stimulation with BSA[4,8].

Investigation of the secondary responses of BX chickens is hindered by the following factors. (1) The low and variable responses of chicks less than 6 weeks old, and the long interval that is required between the first and second

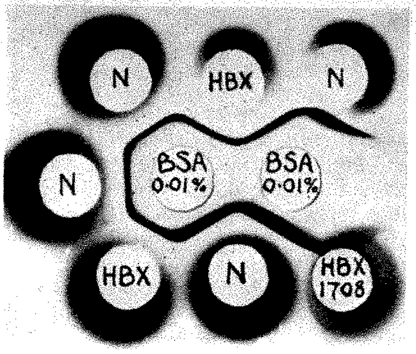

Fig. 1. Reactions in agar (8 per cent sodium chloride) of secondary anti-BSA sera from HBX and control birds against 0·01 per cent BSA.

injections of antigen to elicit a secondary response[9]. (2) Hormonal bursectomy, which is generally considered more effective because it occurs earlier, produces high mortality during the first weeks of life; the survivors may therefore be suspected of having bursal remnants unless these are shown to be absent at examination *post mortem*. (3) These examinations must be made before the bursae of the normal control birds are involuted; the age at which this occurs varies with breed, but bursal regression begins between 3 and 7 weeks and is complete at around 20 weeks[10,11].

Total body irradiation of 2 day old chicks, SBX on the day of hatching, has produced unresponsiveness to repeated injections of BSA, haemocyanin and *Brucella abortus*[12]. These birds were also reported to lack immunoglobulins.

We have studied the primary and secondary responses to soluble antigens injected, either intravenously or subcutaneously in Freund's complete adjuvant, into HBX and SBX chickens—some of which had also been irradiated—and into suitable controls. Primary responses to sheep red cells, tuberculin reactions, immunoglobulin concentrations and changes in peripheral lymphocytes were also examined. The antibody responses of thymectomized (TX) and TX irradiated birds which were included in the study were indistinguishable from those of the normal controls and not reported.

Pure line Light Sussex (LS) or Rhode Island Red (RIR) chicks were used in the experiments involving hormonal bursectomy, and RIR chicks were used in all the others. For hormonal bursectomy, 7 day embryos were injected with 2 mg of testosterone propionate. Surgical bursectomy[13] was performed by Dr B. M. Freeman at hatching or on the following day and thymectomy[14] was performed on the day of hatching. Irradiation with 600 or 700 r. was done by Mr E. A. King, Department of Radiotherapeutics, the conditions being 119 r./min, 220 kV, 15 mamp with a 1 mm aluminium filter.

White blood cell counts[15] were made at approximately weekly intervals for up to 4·5 weeks after hatching. The effectiveness of bursectomy or thymectomy was checked after death and, in some cases, also by histological examination of tissues fixed in formol saline and stained with haematoxylin and eosin. To test for hypersensitivity reactions of the delayed type, chicks were injected intramuscularly with 1 mg of heat-killed *Mycobacterium avium* suspended in liquid paraffin at 4 or 5 weeks of age. At 8 or 9 weeks 0·1 ml. of avian PPD was injected into the wattles and the reactions were noted 24 and 48 h later.

Human serum albumin (HSA) (fraction V, Calbiochem), bovine serum albumin (BSA) (Armour), 2,4-dinitrophenyl bovine gamma globulin (DNP-BGG) prepared according to Eisen[16] and sheep red cells (SRC) were used as antigens; injections were either subcutaneous or intravenous. For subcutaneous injection (BSA, HSA or DNP-BGG), 10 mg of antigen in Freund's complete adjuvant (FCA, Difco) were given twice with an interval of 5 weeks and blood was taken 3 weeks after each injection. For intravenous immunization 30–40 mg/kg body weight of HSA was injected twice with a 7 weeks interval. For the first injection, SRC were suspended in the HSA so that each bird received 1 ml. of a 15 per cent suspension of SRC/kg body weight. Blood was taken 8 days after each intravenous injection.

Tests for precipitating antibodies were made in agar containing 8 per cent or 0·85 per cent sodium chloride to provide a rough guide to the type of antibody formed. Wells 6·0 mm in diameter and 12 mm (centre to centre) apart were used. In passive haemagglutination tests[17], fowl red cells treated with tannic acid and a diluent containing 1·5 per cent heated normal fowl serum were used. Antibodies to SRC were detected by direct and indirect agglutination[18].

Responses of Hormonally Bursectomized Birds given Antigen in Adjuvant

Ten birds (six HBX and four controls) received BSA when 5 and 10 weeks old. Twelve birds (six HBX and six controls) were given DNP-BGG at 12 and 17 weeks of age. The sera obtained 3 weeks after each injection were tested against BSA or BGG and DNP-ovalbumin in Ouchterlony plates. The results obtained in 8 per cent sodium chloride after the second injections are shown in Figs. 1 and 2.

Of the primary anti-BSA sera only two, one HBX and one normal, reacted with antigen. All the secondary sera gave reactions, all but one of which (HBX 1708) were strong.

When primary sera were tested against BGG, 5/6 normal and 3/5 HBX sera formed precipitates. When tested against DNP-ovalbumin none of the control sera and 2/5 of HBX sera gave reactions. All the secondary sera as seen in Fig. 2 had antibodies to DNP, but 2/6 normals and 4/5 HBX sera failed to react with BGG.

Responses of Hormonally Bursectomized and Irradiated Birds given Antigens Intravenously

Approximately half the chicks in this experiment which included thymectomized (TX) birds were irradiated with 600 r. when 2 days old. Mortality was much higher (68, 50 and 75 per cent, respectively) in the TX irradiated, HBX and HBX irradiated groups than in the normal, irradiated or TX groups. At 12 weeks of age, the chickens received an intravenous injection of SRC suspended in HSA and were bled 8 days later. The results of antibody estimations on these sera are shown in Table 1. At 18 weeks the surviving birds were killed and the cloacal region was examined for bursal tissue; the results are included in Table 1.

Immunoelectrophoresis of the sera showed reductions in the gamma globulin bands formed by the sera of 6/9 of the HBX and HBX irradiated birds, and of 2/5 of the

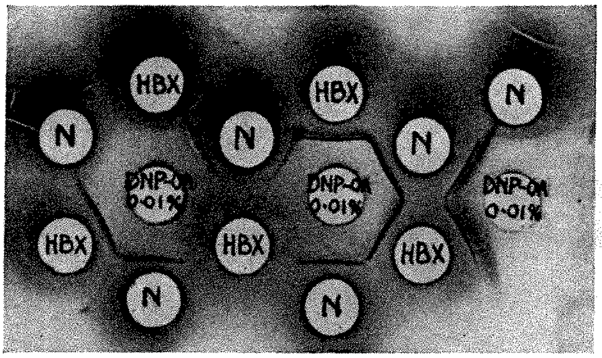

Fig. 2. Reactions in agar (8 per cent sodium chloride) of secondary anti-DNP-BGG sera against 0·01 per cent DNP-ovalbumin.

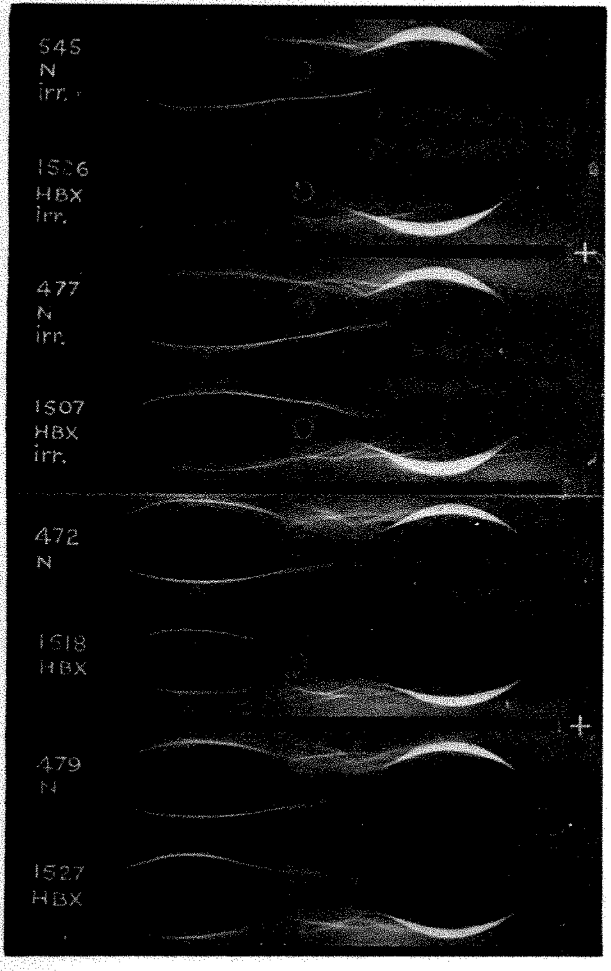

Fig. 3. Immunoelectrophoretic analysis of some representative chicken anti-sera described in Table 1. Rabbit anti-sera to whole fowl serum and to chiefly fowl gamma globulin in alternate troughs. Note varying amounts of gamma globulin detected in HBX and HBX irradiated birds.

irradiated group. Even in these the gamma globulin band could be seen (Fig. 3).

The results in Table 1 show that the response to HSA in the HBX and HBX irradiated groups was much more seriously impaired than that to SRC. Two of these birds (1504 and 1507) had very high titres of anti-HSA by passive haemagglutination but still lacked precipitins. Irradiation alone also seemed to reduce the response to HSA.

Responses of Surgically Bursectomized and Irradiated Birds

The chicks used in this experiment were operated upon on the day of hatching, irradiated on the next day and given their first injection, either of HSA and SRC (intravenous) or of HSA in Freund's adjuvant, when 8 weeks old. Because the primary responses to SRC were identical in all groups (Table 1) the secondary response to SRC was not studied. The second intravenous injection of HSA was given at 15 weeks, and the second adjuvant injection at 13 weeks. Results of antibody estimations for secondary sera are shown in Table 2. After two injections of HSA all twenty-two normal and irradiated birds had formed precipitins compared with 13/22 in SBX+SBX irradiated groups. Of the seven sera which did not precipitate with antigen, two (789 and 792) also had very low passive haemagglutination titres. These two birds were given a single intravenous injection of 1 ml. of 15 per cent SRC to which they responded normally.

Primary responses to HSA in adjuvant were equally low in operated and control birds. Primary responses after intravenous HSA again showed that many more birds were without precipitating antibody in the operated than in the control groups. Mean anti-HSA titres of the SBX and SBX irradiated groups did not differ significantly from those of the control groups, although a few individuals had lower titres than any found in the controls.

No reductions in gamma globulin concentrations, such as those found in some of the HBX sera, were seen even in the sera of the least responsive SBX or SBX irradiated birds.

Effect of Irradiation, Bursectomy and Thymectomy on Peripheral Lymphocytes and Body Weights

The results in Table 3 show that irradiation of normal chicks with 700 r. instead of 600 r. produced a much greater and longer lasting reduction in lymphocytes and substantially lower body weights at 15 weeks. This difference was also found in operated irradiated birds.

Lymphocyte numbers after thymectomy alone had not returned to normal by 25 or 31 days. Neither hormonal nor surgical bursectomy alone had a lasting effect. Thymectomized birds were on the whole more seriously affected with both doses of radiation than their normal controls.

The greatly enhanced susceptibility of the TX birds to irradiation as shown by the depletion of peripheral

Table 1. ANTIBODY RESPONSES OF NORMAL, IRRADIATED, HBX AND HBX IRRADIATED BIRDS AFTER ONE INTRAVENOUS INJECTION OF SRC AND HSA

Group	Bird No.	Anti-HSA Precipitation 8 per cent NaCl*	Anti-HSA Passive haemagglutination	Anti-SRC Direct agglutination	Anti-SRC Indirect agglutination	Gamma globulin levels†	Post-mortem findings Mean bursa weights (g)

lymphocytes and reduced body weights (Table 3) occurred despite the presence of residual thymus tissue in most of the birds. It is also surprising that the TX irradiated (600 r.) birds produced similar amounts of antibody to HSA and SRC as the normal and TX control groups. This is in contrast to the findings of Cooper *et al.*[19].

No fewer than six birds from each of the six groups in the two experiments which included irradiation with 600 or 700 r. were tested for delayed hypersensitivity. Only two failed to react; both were in the TX irradiated (700 r.) group and they also lacked detectable thymus tissue when examined at 22 weeks. There were, however, five additional birds, also devoid of detectable thymus tissue, which gave positive reactions. This differs from the results of Cooper *et al.*[12], who obtained delayed hypersensitivity wattle reactions to diphtheria toxoid in only two out of fourteen TX irradiated birds.

In both experiments, surgical thymectomy combined with irradiation provided more birds (11/32) without detectable thymus tissue at 20 or 22 weeks than surgical thymectomy alone (3/28). The mean weights of the residual thymus tissue were 0·17 g in the TX group given 700 r. and 0·54 g in the corresponding TX group; mean values of the thymus weights of the normal and irradiated control groups were 6·9 g and 4·4 g, respectively.

The results indicate that the inhibition of bursal development with testosterone *in ovo* was more effective than surgical bursectomy combined with irradiation in depressing the primary responses to HSA and SRC. Both procedures suppressed the formation of anti-HSA precipitin, but in addition in the HBX birds only very low concentrations of antibodies to HSA could be detected by tanned cell agglutination; they had reduced anti-SRC titres and 6/9 of them had reduced gamma globulin concentrations, whereas SBX and SBX irradiated birds were normal in these respects.

Inability to form precipitating antibody to BSA after one injection of antigen has been demonstrated in birds bursectomized up to the tenth day after hatching and immunized as late as 22 weeks[8]. In our experiments, the formation of normal amounts of precipitating anti-BSA by 13 week old HBX birds (Fig. 1) after two injections of antigen must therefore be attributed to the mode of immunization. The effect was not a result of the use of adjuvant, because, as Table 2 shows, a second intravenous injection of HSA 7 weeks after the first also produced a normal response.

The presence of natural antibodies to erythrocytes in normal fowl sera is probably caused by unidentified but repeated antigenic stimuli. The response to a first injection of red cells can therefore be considered not to be a true primary response and this may account for the formation of antibody to SRC by our bursaless birds. Janković and Isaković, however, obtained no haemagglutinins after one injection of human O cells[6] although anti-O agglutinins are usually present in fowl sera.

Experiments on antibody production by bursaless chickens involve so many variables (for example, breed, mode of bursectomy, age of immunization, nature of antigen and method of detecting antibody) that they are not strictly comparable. It seems, however, that antibody formation to viruses[20,21], resistance to coccidiosis[22] and the clearance of fowl red cells[8] labelled with chromium-51 and of goat red cells[23] were completely unaffected by bursectomy. The formation of agglutinating antibody to *Leptospira icterohaemorrhagiae*[24], *Salmonella typhimurium* and *Spirochaeta gallinarum*[25] after infection or multiple injections was impaired and possibly delayed but not abolished. The complete absence of detectable antibody after a single antigenic stimulus has been reported for a variety of protein and bacterial antigens[1] The only report of a secondary response to BSA in SBX birds[26] shows that, while primary peak antibody concentrations (at 22 weeks) were 7 per cent of those of the normal controls, this proportion rose to 43 per cent after a second injection at 34 weeks

In our experiments, bursaless birds had seriously impaired primary responses, especially to soluble protein antigen They cannot, however, be considered unresponsive, for they all formed some antibody either to SRC or to soluble protein after a second injection, and they were not agammaglobulinaemic It is apparent that only hormonal (as opposed to surgical, even combined with irradiation) bursectomy early in incubation can produce a marked effect on gamma globulin concentrations and antibody production and that only a small proportion of HBX animals is permanently affected Dr N L Warner (personal communication), starting with thirty-four HBX chicks, had nine still alive at 9 months, only two of which were considered to be agammaglobulinaemic although five did not respond to a fourth injection of *Brucella* organisms

The massive, rapid and transitory antibody response of the fowl to a single intravenous injection of a soluble protein antigen is unlike that of any other species It differs also from subsequent responses of the fowl in the type of immunoglobulins formed[27] It is this unusual type of primary response that seems to be affected by bursectomy

We thank P L Long for providing the testosteronized birds, helping with the thymectomies and for advice on lymphocyte counts, and Dr B M Freeman for carrying out bursectomy E A King, Department of Radiotherapeutics, University of Cambridge, irradiated the birds We thank Miss Jill Saunders and members of the Parasitology Department at Houghton for technical assistance One of us (E O) thanks the Agricultural Research Council for financial support

Genetic Influence on Alimentary Lipaemia in Rats

by
MEYER FRIEDMAN
SANFORD O. BYERS
Harold Brunn Institute,
Mount Zion Hospital and Medical Center,
San Francisco

The response of the concentration of postprandial plasma triglyceride to ingested oil is exaggerated in certain rats. This characteristic can be passed on to the offspring for at least two generations

WHEN studying alimentary lipaemia in the rat[1,2] we noted a few individuals showing very high postprandial plasma triglyceride (PPTG) and a few others showing only a minimal PPTG response When retested, these rats consistently exhibited the same responses, although their fasting or preprandial plasma triglyceride values were unexceptional

We were curious as to whether these opposite responses to oil feeding might be genetically determined, and therefore bred both types through two generations The results of this study are described here

Twenty mature male rats and thirty mature female rats (Long–Evans strain) were each given 3 ml of cottonseed oil by stomach tube once each week for 3 successive weeks The concentrations of plasma triglyceride (TG) before the administration of oil and 6 h after were obtained each week by the method of Van Handel and Zilversmit[3] During these 6 h the rats were housed in the central area of the laboratory to ensure maximal lipaemia[2] The individual TG values of males and females were averaged separately The pre-feeding plasma TG averaged 22 and 24 mg/100 ml and the 6 h PPTG, 98 and 88 mg/100 ml , respectively, in the two groups

Five rats of this male group which exhibited an average concentration of PPTG (143 mg/100 ml) greater than the mean of the total male group by four standard errors were selected and bred with five rats of the female group which exhibited an average PPTG (155 mg/100 ml) greater than the mean of the total female group by four standard errors Five male and five female rats with average PPTG less than the respective means of their groups by four standard errors (average PPTG of each group of five rats 76 and 48 mg/100 ml , respectively) were bred similarly

From these breedings, five litters of rats (forty-eight surviving) were obtained from the "hyperlipaemic" parent rats and a similar number of litters (fifty-two surviving) from the "hypolipaemic" parent rats These offspring will be designated as first generation (F_1) From 95 to 115 days after birth, the F_1 rats were fed oil and their pre- and postprandial plasma TG values were measured each week for 3 weeks For control purposes, rats routinely obtained for general laboratory use were treated in the same way Then, as already described, the eight male rats with the highest concentration of PPTG (average PPTG 339 mg/100 ml) were bred to the eight female rats also with the highest PPTG (average PPTG 205 mg/100 ml) The six F_1 males with the lowest PPTG (average PPTG 31 mg/100 ml) were bred to the six females with the lowest PPTG (average PPTG 55 mg/100 ml)

From this breeding of F_1 rats, eight litters (sixty-seven surviving) were obtained from the hyperlipaemic parents and six litters (fifty-six surviving) from the hypolipaemic parents These second generation offspring (F_2) were allowed to mature and then the three weekly studies of their PPTG values before administration of oil and 6 h after were carried out as already described Again control studies were carried out on rats routinely obtained for general laboratory purposes

When it became apparent that the F_1 rats born of hyperlipaemic parents also showed postprandial hyperlipaemia and those of hypolipaemic parent rats a postprandial relative hypolipaemia, various other investigations were carried out First, ten male F_1 rats born of hyperlipaemic parent rats and nine male F_1 rats born of hypolipaemic parent rats were given 200 mg of tyloxapol ('Triton *WR* 1339') by intravenous injection to determine whether the observed plasma TG responses of each group to oil were a result of differences in their respective rates of hepatic discharge of TG Blood samples obtained before and then 6, 12 and 24 h after injection of tyloxapol were analysed for TG and the pre-administration of 12 and 24 h samples also were analysed for cholesterol[4]

We observed earlier[2] that the environment markedly influences the response of the rat's plasma TG to ingested oil, twenty-four F_1 rats (twelve born of hyperlipaemic and twelve of hypolipaemic parents) were housed in an isolated sound-proof room[2] and again the pre-administration and 6 h PPTG concentrations were measured

To determine whether the observed differences in the PPTG values between offspring of hyperlipaemic and hypolipaemic parents could be the result of differences in TG absorption, fifteen F_1 rats (eight born of hyperlipaemic and the rest of hypolipaemic parents) and eighteen F_2 rats (ten born of hyperlipaemic and the rest of hypolipaemic parents) were given 3 ml. of cottonseed oil which had been labelled by mixing with glyceryl-tri-1-^{14}C-palmitate, containing a total of 300,000–600,000 d p m The rats were bled and killed 6 h after the administration of the labelled oil The entire gastrointestinal tract and liver were removed from all rats (an epididymal fat pad also was removed from the F_1 rats) The amount of fat absorbed from the intestine and the amount of this absorbed fat present as fatty acids in the blood, liver and epididymal fat were calculated as described before[2]. In brief, this consisted of hydrolysing the tissue or plasma sample with 30 per cent KOH 95 per cent ethanol in a 1 1 ratio by volume, extracting the acidified hydrolysate with petroleum ether, evaporating a portion of the petroleum ether extract, dissolving this residue in scintillator solution and counting in a Packard model 3003 scintillation counter

Finally, the blood pressure of twenty-two F_1 rats (ten born of hyperlipaemic and twelve of hypolipaemic parents) and twenty-four F_2 rats (twelve born of hyperlipaemic and twelve of hypolipaemic parents) was measured

Pre- and Postprandial Plasma Triglyceride Values in the Offspring

It was apparent (see Table 1) that the male offspring of hyperlipaemic parents exhibited a far greater average 6 h concentration of PPTG (183 mg/100 ml) than the F_1 male offspring of hypolipaemic parent rats (78 mg/100 ml) and also a significantly greater concentration of PPTG ($P < 0\ 001$) than the ordinary stock control rats (90 mg/100 ml). The average fasting plasma TG of these male rats was, however, no greater than that of the male offspring of the hypolipaemic parent rats or of the control rats This hyperlipaemic response of the F_1 rats, however, was not further intensified (Table 1) in the rats of the second generation

The F_1 male offspring of hypolipaemic parent rats, while exhibiting a much lower 6 h PPTG (78 mg/100 ml) than the offspring of hyperlipaemic parents, did not show (Table 1) a significantly lower value than did the controls (90 mg/100 ml) The F_2 male offspring of hypolipaemic parent rats similarly failed to exhibit a 6 h PPTG significantly lower than that of the control rats No differences were found in the fasting plasma TG values of F_2 and stock rats.

The F_1 female offspring of hyperlipaemic parent rats, while not exhibiting (Table 1) as dramatic a rise in PPTG as did their male counterparts, nevertheless showed an average value (115 mg/100 ml) significantly higher ($P < 0\ 001$) than that (59 mg/100 ml) of the F_1 female offspring of hypolipaemic parent rats or than that (78 mg/100 ml) of the female stock control rats. Again, the F_2 female offspring, like the F_2 male offspring, of hyperlipaemic parent rats failed to exhibit (Table 1) a 6 h PPTG any greater than that shown by their F_1 counterparts The fasting plasma TG values were essentially the same in all groups of rats

The F_1 female offspring of hypolipaemic parents exhibited a 6 h concentration of PPTG (59 mg/100 ml) much less (Table 1) than that shown by F_1 offspring of hyperlipaemic parents and significantly ($P < 0\ 001$) less than that observed in the female control stock rats. The 6 h concentration of PPTG in the F_2 female offspring of hypolipaemic parents was even lower (41 mg/100 ml).

* The average 6 h concentration of PPTG was 143 and 155 mg/100 ml , respectively, in the male and female hyperlipaemic parents of the rats of the first generation The average 6 h concentration of PPTG was 339 and 205 mg/100 ml , respectively, in the male and female hyperlipaemic parents of the rats of the second generation

† The average 6 h concentration of PPTG was 76 and 48 mg/100 ml , respectively, in the male and female hypolipaemic parents of the rats of the first generation The average 6 h concentration of PPTG was 31 and 55 mg/100 ml , respectively, in the male and female hypolipaemic parents of the rats of the second generation

‡ Three separate determinations of plasma TG concentrations were made on 3 successive weeks for each rat, these values were then averaged to obtain the values shown

The serum cholesterol values were approximately the same in the stock control rats, and in both generations of offspring of either type of parent rat.

Response of Plasma Triglyceride and Cholesterol of First Generation Offspring to Tyloxapol

Essentially no significant differences were found between the response to tyloxapol of the nine F_1 offspring of hyperlipaemic parents and those of the nine F_1 offspring of hypolipaemic parents. Although the former group had previously shown an average 6 h concentration of PPTG of 260 mg/100 ml after oil ingestion and the latter group had shown 68 mg/100 ml, their plasma TG values 6 h after injection of tyloxapol were 981 and 959 mg/100 ml, respectively. After 12 h, the respective values were 2,008 and 1,783 mg/100 ml. Similarly, the average serum concentration of cholesterol in these two groups was 342 and 335 mg/100 ml twelve hours after injection of 'Triton', and 483 and 514 mg/100 ml twenty-four hours after injection. These results indicate that the rate of hepatic discharge of triglyceride into blood was approximately the same in the two types of offspring[5].

Effect of Sound-proof Room on Postprandial Responses of First Generation Offspring

Whereas housing twelve F_1 rats of hypolipaemic parents in the isolated sound-proof room did not alter their PPTG response, such housing markedly lowered the PPTG response of twelve F_1 rats of hyperlipaemic parents. Thus the average 6 h concentration of PPTG of the descendants of hypolipaemic parents housed in the central area of the laboratory was 33 mg/100 ml (range 22–57) and was 34 mg/100 ml (range 14–123) when tested in the sound-proof room. On the other hand, the average 6 h PPTG of the twelve rats born of hyperlipaemic parent rats was 169 mg/100 ml (range 96–382) in the central area of the laboratory and only 62 mg/100 ml (range 24–121) in the sound-proof room. In short, the plasma TG responses of these two groups which were so different ($P < 0.001$) when they were tested in the central area became far less so ($P < 0.05$) when outside environmental stimuli were eliminated as far as possible.

Intestinal Absorption and Tissue Distribution of Exogenous Fat

As Table 2 shows, intestinal absorption of fat was not significantly different in first and second generation offspring of hyperlipaemic parent rats and first and second generation offspring of hypolipaemic parent rats. The marked difference that was found in their plasma TG response to ingested oil could not therefore be ascribed to the faster or greater absorption of dietary fat in one of the two groups.

Table 2 ABSORPTION AND DISPOSITION OF FED FAT IN OFFSPRING OF HYPERLIPAEMIC AND HYPOLIPAEMIC RATS

				Absorbed dietary triglyceride fatty acid/6 h		
No of rats	Average weight	6 h PPTG (mg/100 ml)	TG absorbed* (mg/6 h)	Total plasma volume (mg)	Total liver (mg)	Fat pad (mg/g of pad)
A, Offspring of hyperlipaemic rats						
(1) First generation						
8	403	233	1,135	29	88	—
(2) Second generation						
10	405	439	798	50	97	1.54
18	Av 404	347 (103–894) ±58	948 (440–1,623) ±70	41 (10–103) ±6.9	93 (48–130) ±6.6	1.54 (0.57–3.24) ±0.2
B, Offspring of hypolipaemic rats						
(1) First generation						
7	376	57	1,206	7	56	—
(2) Second generation						
8	438	51	660	6	56	1.12
15	Av 408	54 (32–79) ±3.7	914 (360–1,650) ±105	6 (4–9) ±0.6	56 (30–100) ±5.0	1.12 (0.43–2.26) ±0.2

* For method of measurement see text

Table 2 also illustrates that the plasma of the offspring of the hyperlipaemic parent rats contained more than six times as much exogenously derived fatty acids as the plasma of the offspring of the hypolipaemic parent rats despite the approximate equivalence of fat absorption in these two groups. Also the content of exogenously derived fatty acids in the liver was significantly greater in the first than in the second group, although the epididymal fat pads of each group contained approximately the same amount of fed fatty acids.

Blood Pressure in the Two Generations

This measurement was taken because the offspring of the hyperlipaemic parent rats usually appeared to be considerably more excitable than the offspring of the hypolipaemic parent rats. The average blood pressure of the twenty-two male offspring rats of hyperlipaemic parent rats (ten were of the first and the rest of the second generation) was 136 mm of mercury (range. 126–162) and that of twenty-four male offspring of hypolipaemic parents (half of the first and half of the second generation) was 118 mm of mercury (range 98–140). This difference was significant ($P < 0.001$).

Our observations indicate that an exaggerated PPTG response, which is found in certain rats, can be passed on for at least two generations to their offspring (particularly the male members). These observations also suggest that a diminished PPTG response of rats may also be transmitted to their progeny.

This seemingly inherited abnormal response to ingestion of exogenous fat does not, however, seem to be the result of any change in the metabolism of endogenous fat, for not only is the fasting plasma TG unaltered in both the hyperlipaemic and hypolipaemic reactors but also the hepatic discharge of endogenously produced fat as determined by the tyloxapol technique[5] is normal.

These observations also make it clear that the intestinal absorption of fat in the hyperlipaemic rat is the same as that in the hypolipaemic rat although the plasma and liver of the former contain far more fat derived from a single ingestion of oil than the comparable tissues of the latter type of rat. Seemingly, the hyperlipaemic rat fails to metabolize the same quantity of absorbed fat as rapidly as the hypolipaemic animal.

We have already reported[2] that external environmental factors are very important in the rat's ability to handle a given amount of fat—an indication that the central nervous system is capable of playing a very significant part in an animal's handling of exogenously derived fat. This is emphasized here because we suspect that the offspring of the original hyperlipaemic and hypolipaemic parent rats have not inherited any fixed or permanent defect either in their metabolism of endogenous fat or in their disposition of exogenously derived fat, but rather a neurogenic or psychogenic propensity to over-react or under-react to aspects of the external environment which influence the concentration of plasma lipid. We believe this to be the possible mechanism because there was no indication of any intrinsic derangement of fat metabolism and especially because the exaggerated concentration of PPTG in the hyperlipaemic offspring almost disappeared when they were isolated in the sound-proof room. Then, too, these same rats seemed in general to be more excitable and to have a higher blood pressure than the hypolipaemic offspring.

RNA Changes in Goldfish Brain during Learning

by
V E. SHASHOUA
Massachusetts Institute of Technology,
Cambridge,
Massachusetts, USA

Acquisition of new swimming skills by goldfish during learning experiments is accompanied by changes in the base ratio of RNA Several hypotheses are put forward to explain these changes

SEVERAL studies[1-13] have correlated RNA and protein synthesis in the brain with the acquisition and retention of learned behaviour. Hyden and Egyhazi[1-4] were the first to show synthesis of an RNA with a unique base composition during learning Flexner, Flexner and Stellar[7], in studies of learning in mice, noted that inhibitors of protein synthesis could prevent the fixation of learned behaviour. Similar effects have been observed by Agranoff, Davis and Brink[10] in studies of learning in goldfish Implicit in these experiments was the hypothesis that the establishment of memory is at least a two step process the first is the acquisition phase which does not seem to require protein synthesis in mice[11] and goldfish[13], and the second is a consolidation step which can be inhibited by drugs which prevent protein synthesis

The results of these studies imply that RNA is involved during learning In particular, it is important to find out whether the RNA base ratio changes which can be observed are biochemical correlates of learning or if they are caused by some non-specific factors such as stress or use This article attempts to correlate the acquisition and storage of a new swimming skill with the composition of newly synthesized RNA in goldfish brain

By using orotic acid labelled with tritium as the precursor of uridine and cytidine, the RNA which was formed during learning was isolated and its base composition was determined in order to give the ratios of uridine to cytidine The task for this study was chosen so that it gave a large challenge to the goldfish brain to produce maximal changes in RNA synthesis, thus any unique base composition could be detected in analyses of whole brain extracts

Goldfish ('Comet' variety) measuring 7–8 cm in length and weighing 7–8 g were used throughout this study The animals were fed 24 h before each experiment Groups of seven experimental and seven control fish were placed in separate 5 gallon tanks each of which was filled with 3 gallons of water Orotic acid (10 µc, specific activity 250 mc /mmole) dissolved in 10 µl of 0 15 normal sodium chloride was injected into the ventricle below the region of the optic tectum After injection of the label the goldfish were trained to swim in a new pattern by attaching a foamed polystyrene float to a suture at the ventral surface of the fish, 1 mm caudal to the base of the first pair of lateral fins A 0 7 cm cube was used for a 7 g fish. The sequence of adaptation of a goldfish to the challenge which was produced by the float is shown in Fig 1 The animal acquired new swimming skills during the challenge In stage I the animal is pulled up to the surface in either of two configurations, one with the head out of the water and the other in an upside down position This is a very noxious stimulus and the fish try to escape to the bottom of the tank, but the float pulls them up Thus stage I is characterized by considerable struggling Stage II is usually attained within 1 h Here the animals assume a 45° angle and swim constantly to avoid being turned upside down by the float At stage III, the goldfish have become sufficiently skilful to swim horizontally with the float in a ventral position Frequently, the tails are bent to one side to compensate for the lateral torque imposed by the float The fish constantly swim in this position One can readily observe that the pattern of motion of the lateral fins is quite different from that of controls In each experiment, the controls received a suture at the same position as the experimental groups but no float In considering the various aspects of the adaptation of the fish to the task, one can postulate influences on many parts of the brain, including motor areas, cerebellum, optic tectum, vestibular regions (Mauthner cell) and certainly controls of visceral functions especially the modulation of the air content of the swim bladder

The use of orotic acid in these experiments resulted in the formation of labelled UTP and CTP as the precursors for RNA synthesis[14] In the conditions of the experiment only about 10,000 c p m of the label became associ-

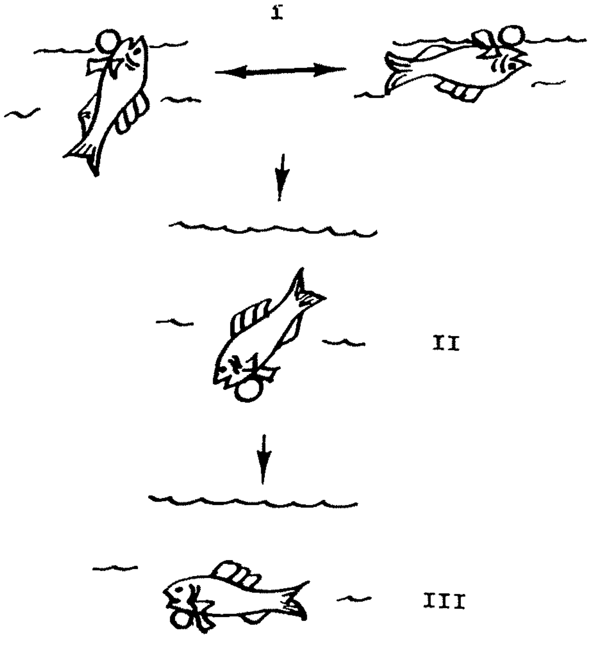

Fig 1 Stages in the adaptation of a goldfish to the float

ated with each animal brain Of this, on an average, 1,000 c p m of label was incorporated into phenol extractable RNA After completion of a 4 h training period the animals were decapitated, the brains were washed with distilled water and homogenized with a 'Dounce' homogenizer in 0 02 molar phosphate buffer (*p*H 7 2) containing 0 5 per cent sodium lauryl sulphate The pooled brain homogenates from seven animals were extracted with hot phenol (60° C) in order to isolate the nuclear RNA according to the methods of Scherrer and Darnell[15] and Perry[16] The product was purified by alcohol precipitation to give an RNA with a sucrose density gradient pattern which was characteristic of nuclear RNA[20] The purified RNA was analysed for total radioactivity as trichloroacetic acid precipitable counts, for total quantity of RNA as absorption at 260 mμ and for base composition after alkaline hydrolysis (0 3 molar potassium hydroxide for 17 h at 37° C) using paper electrophoresis[17]

Fig 2*A* shows that the task used in this paper has a learning component which is remembered by the goldfish after 22 h The results for experiment *A* were obtained for a group of ten animals each with a different coloured float and suture so that each animal could be identified and rechallenged with the same float on the second trial The animals were observed at fixed times during the 4 h training period and those at stage I, stage II and stage III (Fig 1) were arbitrarily scored at 0 per cent, 50 per cent and 100 per cent trained At each test time the group score was obtained and plotted to give the learning curve for trial I in Fig 2*A* After 4 h the floats were removed from the fish, and 22 h later the fish were tested again with the same floats to give curve II in Fig 2*A* The faster rate of learning on the second trial clearly shows retention, that is, the mean time for trial II was 21 ± 4 min as compared with 156 ± 13 min in trial I ($P <$ 0 01 in a *t* test)

Fig 2*B* is a repeat of these training and testing experiments using a separate group of animals each of which received a dose of 120 μg of puromycin 1 5 h before trial I The results show that the rate of acquisition of the task is not significantly altered from that of the group in trial I (Fig 2*A*) and that there is no significant evidence of remembering the task 22 h later, that is, a score in trial II of 100 ± 20 min is not statistically different ($P >$ 0 05) from the score in trial I of 136 ± 13 min The dose of puromycin in this experiment has been previously reported by Brink, Davis and Agranoff[18] to inhibit 80 per cent of the protein synthesis in goldfish brain within 1 5 h Thus inhibition of protein synthesis in the behavioural task of this experiment resulted in no significant retention of the training after 22 h

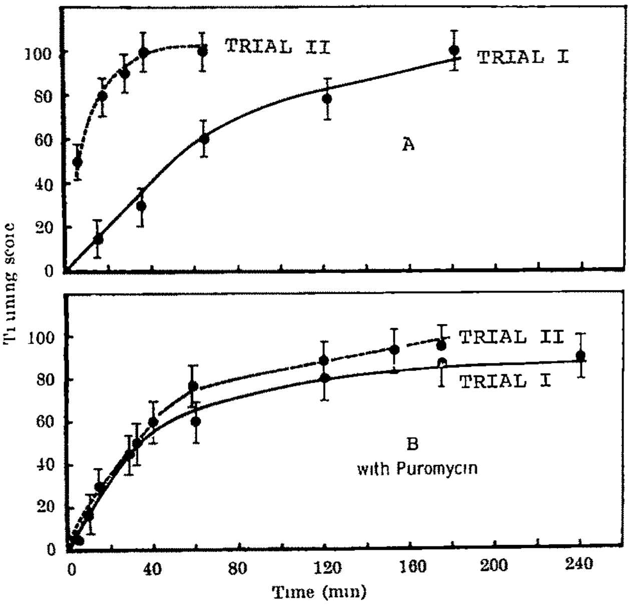

Fig 2 Learning (trial I) and retention (trial II) curves for the goldfish Each curve was obtained on a group of ten animals Trial II was 22 h after trial I (see text) *A*, Experiment *A* with no drugs, *B* experiment *B* group received 120 μg of puromycin (intracranial) 1 5 h before the beginning of trial I

Table 1 summarizes the RNA base ratio measurements for seventy animals, thirty-five experimental and thirty-five control The results show a consistent pattern of increase in the uridine cytidine $(U/C)_E$ values for the experimental group over the $(U/C)_C$ control group values The average values for $(U/C)_E$ minus $(U/C)_C$ are 3 3 with a corresponding mean increase of 96 per cent These base ratio changes, however, do not occur when the animals are first injected with puromycin (see Table 2) The data suggest that the new RNA synthesis accompanying the task has an increased uridine (by about a factor of 3) over its cytidine content

Table 1 SUMMARY BASE RATIO MEASUREMENTS

No	c p m Up	Cp	U/C	$(U/C)_E-$ $(U/C)_C$	% Change

Puromycin dose = 170 μg (intercranial) 1 5 h before training Fourteen animals were used for each datum point

* $(U/C)_E-(U/C)_C$ represents the difference between the uridine to cytidine ratios in experimental and control groups

In this behavioural experiment, the experimental group of goldfish was under constant stress They also performed much work in addition to learning a new swimming skill Thus each of the variables—stress, work, learning or all three—could be responsible for promoting the RNA base ratio changes which were observed Because the animals which were under the influence of puromycin seemed to acquire the swimming skill at about the same rate as those without the drug, they must necessarily have been exposed to approximately the same level of stress and work Moreover, when tested 22 h later, these animals showed no significant evidence of remembering the task In addition the puromycin group showed no significant base ratio changes (Table 2) after the acquisition of the new swimming skill It follows therefore that the changes in RNA base ratio are probably the result of the learning component of this behavioural experiment and not caused by general factors such as work or stress

These data suggest that RNA base ratio changes accompany the acquisition stage of learning and imply that protein synthesis is required for the establishment of these changes Recent observations[19], however, that puromycin produces hippocampal seizures in rat brain, in addition to inhibition of protein synthesis, indicate caution on this point The RNA results are similar to the biochemical findings of Hyden and Egyhazi[3] concerning the experiment on transfer of handedness in rat brain

There are a number of possibilities for explaining the RNA base ratio changes which are observed as the concomitant biochemical change with the acquisition of new swimming skills by the goldfish For example, the behavioural task could merely lead to changes in the metabolic pools of CTP and UTP to produce the base ratio changes in the RNA This, however, is ruled out by direct measurements of the UTP and CTP contents of the metabolic pools (my unpublished work)

Another possibility is that learning causes specific instructional changes in the newly synthesized RNA A more attractive hypothesis is that the brain operates in many functional states such as sleep, wakefulness, learning, and so on, each of which is biochemically distinct Thus the biochemical consequences of learning could result in an induction at the genome level of a special RNA which is required for promoting such processes as neuronal growth which could occur during the consolidation step of learning Only further experimental evidence can distinguish which of these mechanisms or alternative processes are the correct biochemical correlates of learning

This work was carried out during an appointment as resident scientist in the Massachusetts Institute of Technology Neurosciences Research Program

Evolution of the MG

by
ROBERT ROWLAND
Department of Geology,
University of California, Davis

Evolutionary principles can be applied to the development of the sportscar of the genus MG after its migration to the United States

THIS article aims to examine the development of the MG sportscar in the light of modern evolutionary thought It is obvious that the application of biological principles to a man-made, profit-oriented item will require a degree of extrapolation It seems worthwhile, however, to stretch a principle to a seemingly inapplicable situation if it allows us to examine more clearly the principle itself

The name MG derives from the initials of the Morris Garages, where the first cars were fabricated in 1923, based on parts from Morris automobiles. The company continues this semi-independent role, combining parts of its own manufacture with those available from other producers

At various times, the company has produced small sedans in addition to the sportscars Their production is not the chief endeavour of the company, but rather these sedans represent the attachment of the MG name with connotations of sporting flavour to cars similar to others being produced concurrently This situation is analogous to a perverted form of Batesian mimicry where a relatively distasteful form, the sedan, seeks to imitate a more tasteful form, the sportscar, to increase predation—that is, buying pressure—on itself

Basic to our discussion is the establishment of the breed of MGs relative to some taxonomic level Although obviously asexual, their phylogenetic pattern and progressive development prompt their consideration as a sexual organism The development of a working hypothesis treating the entire MG lineage as a genus with each model representing a species may allow us the flexibility to develop meaningful analogies

The phylogenetic tree (ref 1, Fig 1), reproduced here with recent additions, will be useful in reviewing the history of production As with the palaeontological record, however, recent forms provide the most information about competition, habitats and development Consequently, the succeeding illustrations will involve the models produced since the Second World War—the MG-TC (Fig 2*a*)—and its derivations

The first MG-TC migrated to the United States in the hands of private owners, these founders survived in this large, competition-free habitat These cars were followed by others imported through an embryonic dealership system Priced at less than $2,000 in the period 1947 to 1949, they sold readily, particularly in the eastern and southwestern parts of the country This model was not perfectly pre-adapted to the new and prosperous habitat it found in America All MG-TCs were produced for home use only and consequently were equipped with right-hand drive (Fig 2*a*) In the United States there must have been strong selection against this factor To pass another car, the driver had to swing far left in order to have a full view of the oncoming traffic Information regarding the head-on collisions which frequently resulted was relayed to the factory

The company, to increase its profits, would have to adapt itself to extend the product to the limits of its niche This exploitation is analogous to the tendency of any group of animals to spread themselves throughout the resource area

The factory which contains the component parts for production of species is analogous to a gene pool The influx of profits from American sales took the form of information which was combined with the efforts of the engineers (egg-heads) at the factory to produce a new species This species—the MG-TD—was more streamlined and would be offered to American buyers with left-hand drive (Fig 2*b*)

These events are comparable with the Baldwin effect, in which an organism is able to stay in a favourable environment until genetic fixation achieves suitable modification of the phenotype

During the last years of TD production the TD Mark II model with increased horsepower was offered as well as the standard model This increase with additional streamlining and more comfort for the passenger was incorporated into the model TF (Fig 2*c*) This speciation was not based on geographic factors as in the TC–TD situation, but was adaptive in nature The TF model continued until 1955 when the effects of the American horsepower race and increased competition from Triumph sportscars indicated that adaptation would be necessary if the breed was to survive

Although the T-series cars had undergone progressive increases in power and slight changes of streamlining and styling, the overall body shape of clamshell fenders, running boards and the absence of luggage space was strongly characteristic of pre-war automobiles The modern envelope body style had been experimented with as early as 1951 Test data indicated that continued use of TF engines and chassis with simple substitution of a streamlined body would allow a 12 mile/h gain in top speed (Fig 3, from Thornley, ref 1) with an appropriate gain in acceleration times This model which consisted of a new body shell over unchanged mechanical components was designated as the MGA (Fig 2*d*) This speciation can be compared with a problem in palaeontology where a slight difference in total genetic make-up produced an

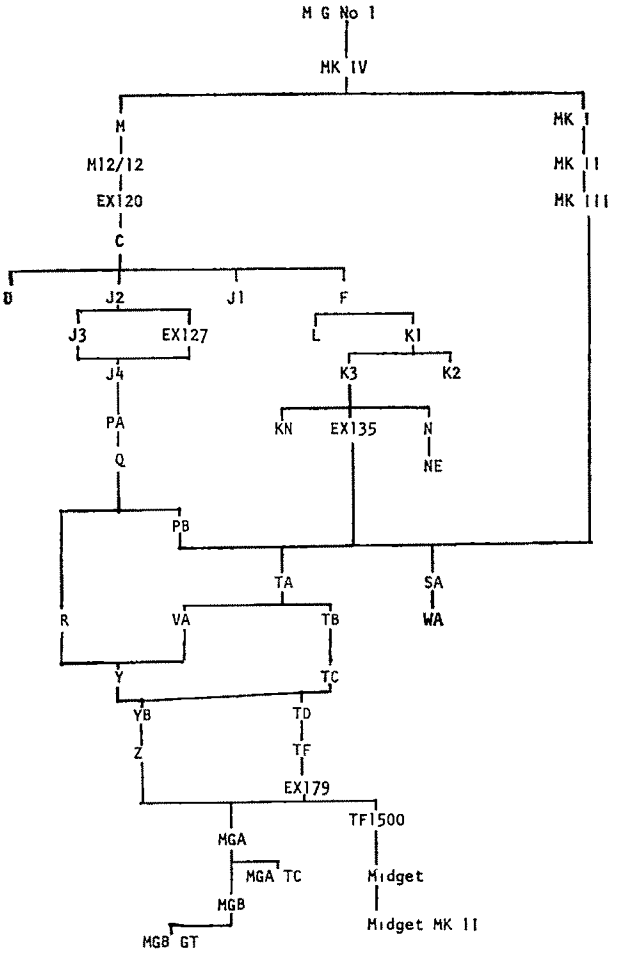

Fig 1 Phylogenetic pattern of the MG automobiles (after Thornley, ref 1)

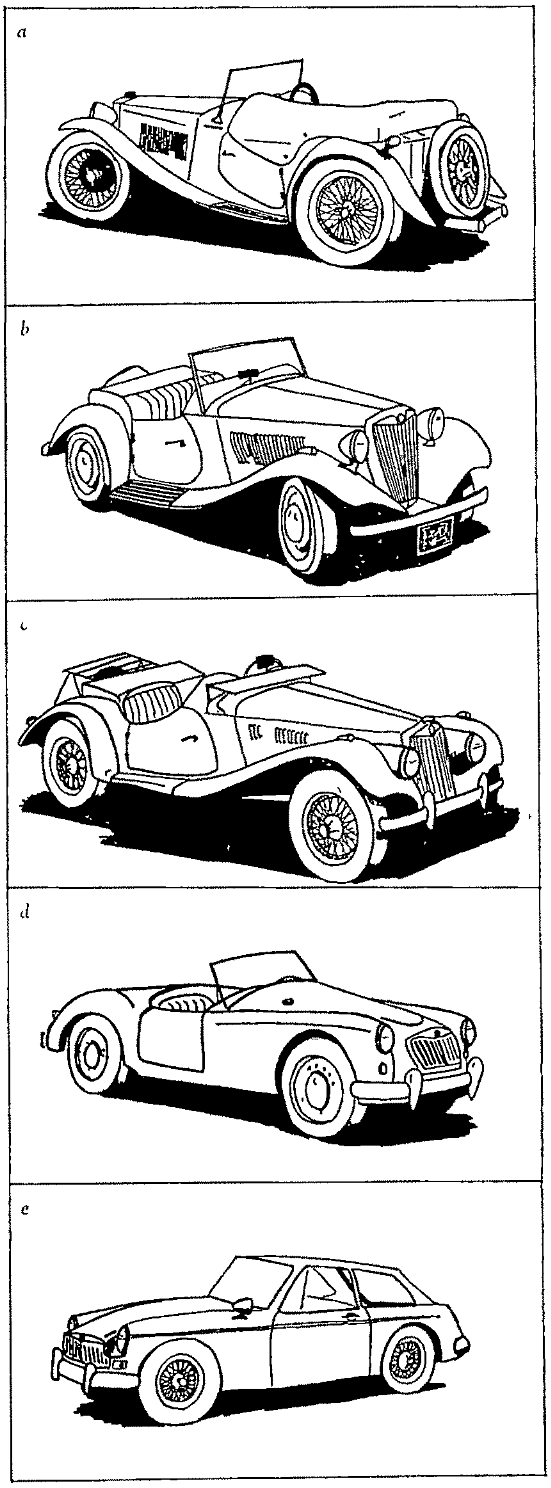

Fig 2 MG models, *a*, MG-TC, *b*, MG-TD, *c*, MG-TF, *d*, MGA, *e*, MGB-GT

entirely changed shell which, if found without the internal organs, would show little affinity to its predecessors

The basic MGA body design remained in production for more than 8 yr During the production, slight changes in the genetic make-up were enacted The power of the engine was increased and there were small phenotypic changes in the design of the grille and the placement of the tail-light The duration of this body style suggests that there was a selective premium for the maintenance of the phenotype and that the variations that developed during the 8 yr period are analogous to sibling species

The MGA Twin-Cam, essentially an MGA with a highly developed twin-overhead camshaft engine and racing-type suspension, was produced from 1958 to 1961 The price of these cars was in excess of $4,000, nearly twice the price of the standard model MGs, since their introduction, had been the basis of the low-priced sportscar market, although the MGA was at this time costing $600–$800 more than the first TC models The MGA-TC was not in the low-priced category and found itself in direct competition with the Jaguar models with which it had sympatrically existed since the early 1950s The direct competition with another genus highly adapted to its niche resulted in extinction of this species The gene pool did not continue to produce a model obviously incapable of surviving the selection pressures Finding that the high-priced niches could not be invaded, the factory turned to lower-priced niches for additional exploitation

In 1962 the MG Midget was introduced The MGA was not referred to as a midget series car, possibly because the price, in dollars, and the weight, in pounds, both exceeded 2,000, unlike the earlier TC–TD–TF models The reintroduction of the Midget, the price and weight of which were less than 2,000, met with less competition and flourished Some of this success is in part analogous to the Batesian-type mimicry presented earlier in the discussion of sedan production

Production of MGAs continued until 1963 During the 8 yr of its production both the quantity and quality of competition improved These factors brought about the necessity for more adaptation if the marque was to survive The economic pressure to maintain a mid-$2,000 price was relieved slightly by the concurrently produced Midget model, consequently, the new species could represent a departure from the standard price category The species developed was the MGB (Fig 2e), produced according to styling trends established by Jaguar's successful XK–E model, offered with a slight increase of horsepower over the MGA and with roll-up windows The current price of this car is about $3,000, well below Jaguar's niche and there is no direct competition between these two genera

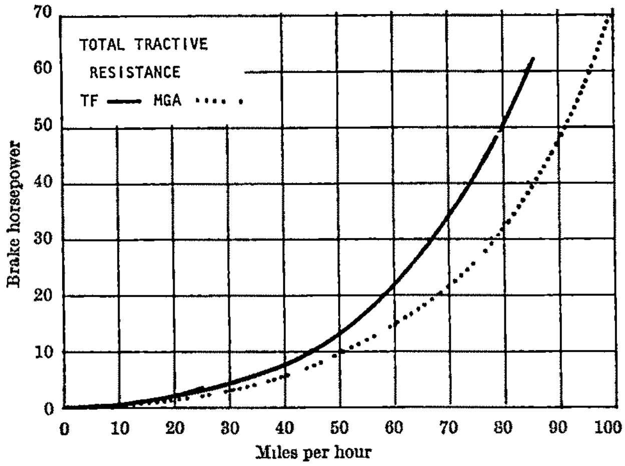

Fig 3 Total tractive resistance curves At 50 horsepower the MGA body style allowed an increase of 10 miles/h over the TF model (from ref 1)

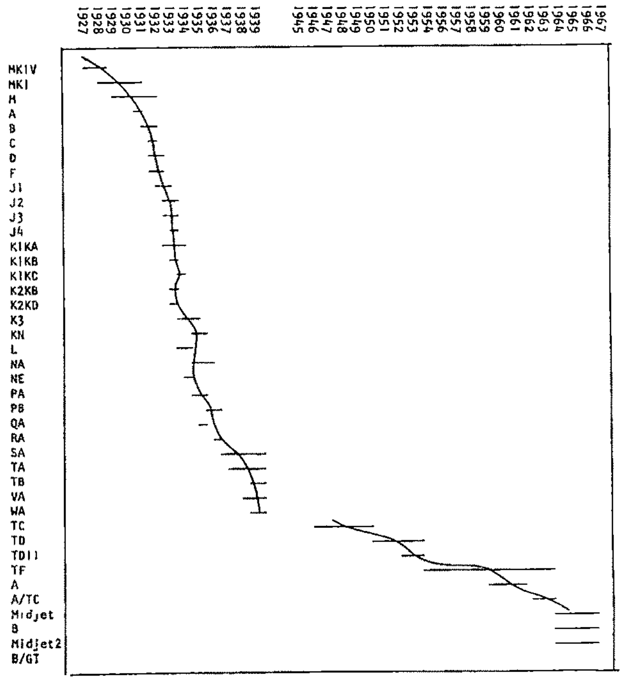

Fig 4 Life span chart of models produced (after Thornley, ref 1)

In 1966 an additional form of the MGB was introduced, the MGB-GT with non-removable steel top (Fig 2e) It remains to be seen if this more protected model, an ecological polymorph, gains popularity in areas where the climate is not compatible with the soft-top varieties

This topic is an obvious stretching of scientific investigation The basic weakness in this proposed analogy is the lack of concrete, supportable data Thornley's book did provide some data and graphs which are included here, but it did not contain the actual production figures which would have allowed insight into population characteristics of the breed

Individual instances analogous to Batesian mimicry, palaeospecies, genetic structure, the Founder principle, pre-adaptation, gene pools, the Baldwin effect, sibling species, species extinction and ecological polymorphism were recognized

The overall structure of the various species is presented (Fig 4). A curve approximating the centre points of the life span of each species indicates that the more recently produced species have had longer life spans and that the rate of evolution before the Second World War is not necessary for the genus to survive As long as the output of the gene pool is successful in finding and holding a niche the stability continues The sale of automobiles to the public is the stabilizing factor and the rate at which each car produced is sold relates information to the gene pool Information flow back to the gene pool in the form of money indicates a successful product If the breeding rate decreases, the gene pool attempts to reorganize itself to produce a new species which, if successful, will carry on the lineage

Evolution is a real process and, as can be seen from this article, similar processes can be shown to exist in man-made products To what degree does this simulated evolution affect the thinking of evolutionary workers who knowingly or unknowingly live in an environment where evolution is fallaciously applied ?

LETTERS TO THE EDITOR

PLANETARY SCIENCE

Metals on the Lunar Surface

IN a recent paper[1] written before the flight of Surveyor V, I suggested that metallic iron, aluminium and magnesium may exist on the lunar surface as a result of the chemical reduction of the surface by atomic hydrogen accumulated from long bombardment by solar wind protons. The large number of hydrogen atoms available and the continuous turnover of the lunar surface layer throughout the ages led me to suggest that there is a layer a few feet thick which contains metals.

Assuming an arbitrarily chosen lunar composition of $5FeO\ 2Al_2O_3\ 5MgO\ 20SiO_2$, I estimated the range of 1 to 2 keV protons in this material to be about 150 Å. The total number of oxygen atoms, which is rather insensitive to composition, is about 7×10^{16} cm^{-2}. Assuming a solar wind flux of 3×10^{8} protons cm^{-2} sec^{-1}, the number of hydrogen atoms available in a layer of 150 Å material during a period of 15 yr will be twice the number of the combined oxygen atoms.

Thermodynamically, the reduction of oxides by atomic hydrogen to form metals or elements and water vapour is energetically favourable. For example, the values of free energy for the reduction (by atomic hydrogen) of the oxides, magnesium oxide, calcium oxide, ferrous oxide, aluminium oxide and silicon dioxide are −14·9, −6·3, −91·3, −74·3 and −96·4 kcal/mole, respectively, at 400° K. The free energy values for silicates or combined oxides at 400° K as well as 100° K and 298° K are not materially different from those of single oxides. Atomic hydrogen is known to be very active chemically and there were indications in the laboratory that iron oxides can be reduced to lower oxidation states or to metal by protons of a few keV energy[2]. It is therefore reasonable to suggest that the oxides or silicates on the lunar surface are reduced to elements by hydrogen from the Sun, and that the water produced diffuses out to the surface through a layer less than 150 Å thick and escapes to the vacuum above. The reverse reaction of water on aluminium and magnesium to form molecular hydrogen is thermodynamically favourable. Because, however, atomic hydrogen is continuously supplied and water, under vacuum, escapes easily and continuously, the formation of metallic elements should be favoured in the long bombardment. It may be noted that the proton bombardment also causes sputtering. This effect, however, is relatively insignificant.

If we arbitrarily quintuple the time of reduction or the amount of hydrogen atoms required for reduction and also assume that the Moon has been bombarded by solar wind for $4·5\times 10^{9}$ yr, the incident flux of hydrogen is capable of reducing a layer of silicates as thick as 1 m. If the lunar surface layer is stagnant, the reduction reaction cannot occur much deeper than the range of protons. Most selenologists, however, believe that there is a continuous flow or turnover of the surface material because of meteorite bombardment or volcanic action. The thickness of lunar "dust" is not known, but the best estimate by Newell[3] is about 1 m. If it is assumed that a layer 1 m thick was turned over once completely and uniformly during the life of the Moon, it is likely that a fraction of the material exists in an elemental or metallic form, or in some kind of reduced state.

Magnesium and aluminium, if present, are valuable because of their high energy content and structural value. These metals, after collection, could be heated with the readily available silicates on the Moon. The silicon dioxide component in the silicates could serve as an oxidizing agent and when the reactions occur a large amount of energy would be liberated. In addition to metallic magnesium and aluminium, metallic iron would certainly be present. This iron powder can easily be separated magnetically and may be used as structural material. Whether elemental silicon is present is a difficult matter to determine because silicon may form volatile silanes when reacting with hydrogen.

Another aspect of the possible presence of these reduced materials concerns the safety of the astronauts. The metals, if present, must be quite loose in structure and have large surface area. If astronauts should carry some of these loose materials into a space cabin, these materials may burn spontaneously in an oxygen atmosphere.

The recent results of Surveyor V (ref 4) seem to substantiate in part this hypothesis. From the magnet experiment, Wys[4] estimated that lunar surface material may contain 1 per cent by volume of metallic iron. If the lunar surface material has a chemical composition similar to that of terrestrial basalts, this is equivalent to more than 3 per cent by weight and the metallic form constitutes more than 30 per cent of the total iron—a surprisingly high percentage. Because some meteorites are known to contain metallic iron, its high content in the lunar surface could not be attributed entirely to the hydrogen reduction suggestion. Furthermore, the magnetic material present on the lunar surface may be also attributed to magnetite instead of metallic iron. An examination of the analysis of the lunar surface by Turkevich *et al*[4], however, also seems to give evidence that the lunar surface material is deficient in oxygen or rich in metal.

Turkevich *et al*[4] gave the chemical composition, in atomic per cent, of the lunar surface at the Surveyor V site as follows: carbon, <3, sodium, <2, magnesium, 3±3, aluminium, 6·5±2, silicon, 18·5±3, 28 <A <65, 13±3, A >65, <0·5, and O, 58±5, where A represents any element with its mass number as indicated. The composition compares favourably with that of terrestrial basalts, and Gault *et al*[4] stated that this finding "is consistent with a widely accepted hypothesis that extensive volcanic flows have been responsible for flooding and filling of the mare basins".

Although the errors of the chemical composition are large, some confidence may be placed on the experimentally assigned values because they seem to match well with that of basalts. If these figures are taken as close to the true values, the amount of oxygen required to satisfy the valency of the electropositive elements in the lunar analysis can be estimated. In such an estimation, I conservatively assume that carbon does not take up any combined oxygen because it may form carbides instead of carbonates. On the other hand, because the terrestrial basalts contain about 2 per cent of sodium, we allocate 1 per cent oxygen for sodium in our estimate. A study of the terrestrial basalts indicates that for all elements with mass number above 28, the average oxygen requirement is more than unity. This is particularly true because basalt contains some ferric oxide and very little sulphur and potassium. We conservatively assign one oxygen atom to each atom of elements above mass 28. The total oxygen required to balance all the electropositive elements was calculated to be 64·3 "atomic per cent" as compared with the experimentally measured value of 58. The Surveyor V experiment could not measure the hydrogen content and the terrestrial basalts do contain about 4 atomic per cent of hydrogen equivalent to 2 atomic per cent of oxygen. Because there is indication that the lunar surface is volcanic in origin, it is reasonable to assume that the lunar surface material contains little or no hydrogen.

If the electropositive elements are partially reduced, the extent of the reduction can be estimated by matching the oxygen required to the experimentally measured oxygen content. A simple calculation indicates that 10 per cent to 20 per cent of the elements are in an elemental form, depending on whether one assumes that silicon is also reduced to elemental form or escapes into space as silanes. While it is not certain that aluminium and magnesium may exist as metals, this argument is certainly not inconsistent with the information at present available.

General Relationship between Suspended Sediment Concentration and Water Discharge in the Alpenrhein and some other Rivers

IN order to make a long-term prediction of sedimentation in Lake Constance (Central Europe), about five hundred measurements of the suspended load in the Rhine ("Alpenrhein") at Lustenau, Austria (Fig. 1), have been carried out[1,2] at different water levels.

The Alpenrhein drains a total area of 6,122 km², a chiefly mountainous region in the Northern Alps of Switzerland and Austria. According to Waibel[3], between 1931 and 1960 the average water flow was 223.6 m³/sec and the average suspended sediment load was 454.1 mg/l. Thus the river supplied an average annual suspended sediment load of 3.334×10^6 tons, the bulk of which is deposited in the Obersee of Lake Constance[4]. As in most other rivers in humid climates, the bed load carried into the lake can be ignored because it only amounts to about 1 per cent of the total sediment load.

The concentration of suspended sediment load, C_s (mg/l), in the Alpenrhein is strongly related to the water discharge, Q (m³/sec): with increasing water discharge, and increasing flow velocity, the suspended sediment load increases rapidly (Fig. 2).

On a double logarithmic scale this relation can be expressed by a straight line. Its equation is

$$C_s \text{ (Alpenrhein at Lustenau)} = 0.004 \quad Q^{2.2}$$

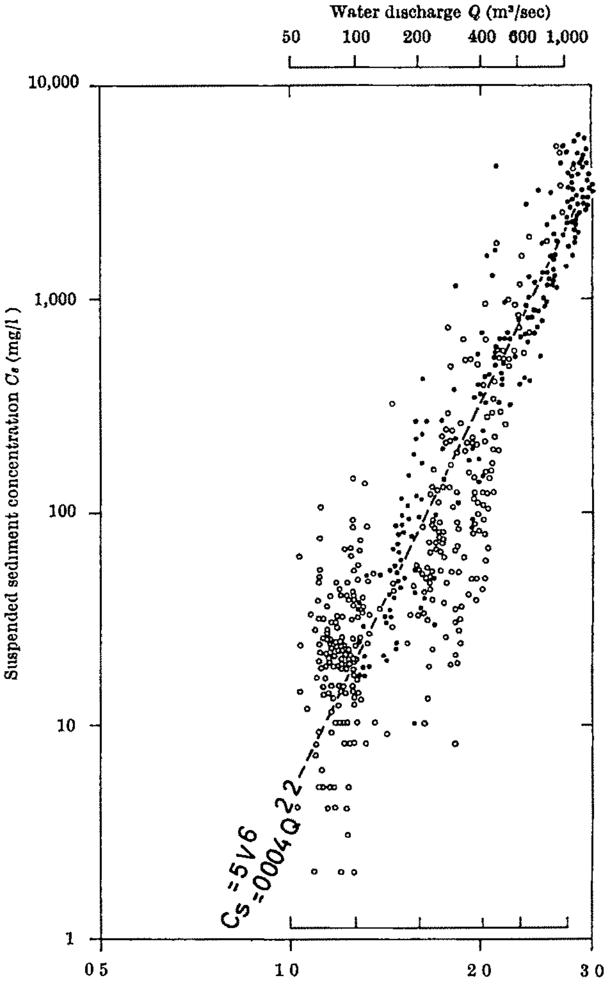

Fig. 2. Suspended sediment concentration versus flow velocity and water discharge in the Alpenrhein at Lustenau (Austria). ●, This communication; ○, Muller, 1965.

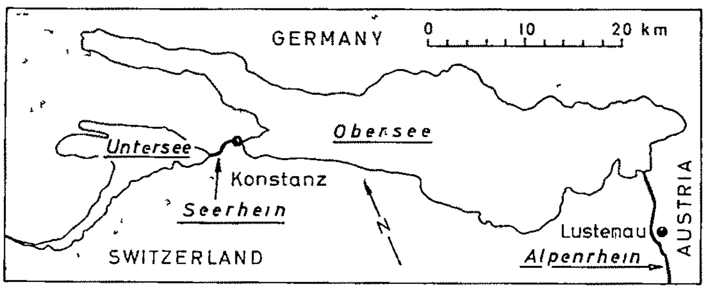

Fig. 1. Lake Constance with Alpenrhein and Seerhein. Sampling stations Lustenau (Austria) and Konstanz (Germany).

The Seerhein is the natural effluent of the Alpenrhein (and of other smaller rivers flowing into the Obersee); it connects the Obersee with the Untersee of Lake Constance (Fig. 1). Because all sand and silt sized material as well as most of the clay sized material has been deposited in the Obersee, the concentration of sediment load in the Seerhein is extremely low. About three hundred measurements of the suspended sediment load in the Seerhein[1] resulted in the equation

$$C_s \text{ (Seerhein at Konstanz)} = 0.20 \quad Q^{0}$$

Data for other rivers were collected from the literature[5-9] and evaluated similarly (Fig. 3, Table 1). In all cases where sufficient measurements had been made over a long period of time, similar relations could be obtained. They can all be covered by a general empirical equation

$$C_s = a \quad Q^b$$

In the rivers concerned, the factor a ranges between 0.004 in the Alpenrhein at Lustenau and 80,000 in the Rio Puerco at Bernardo. The exponent b varies between 1.1 in the Seerhein at Konstanz to 2.5 in the White River in the Mt. Rainier area.

Because the water discharge of a river at a defined cross-section is a function of its flow velocity (Manning equation), a relationship also exists between the suspended sediment load and the flow velocity, V (m/sec),

$$C_s = x \quad V^y$$

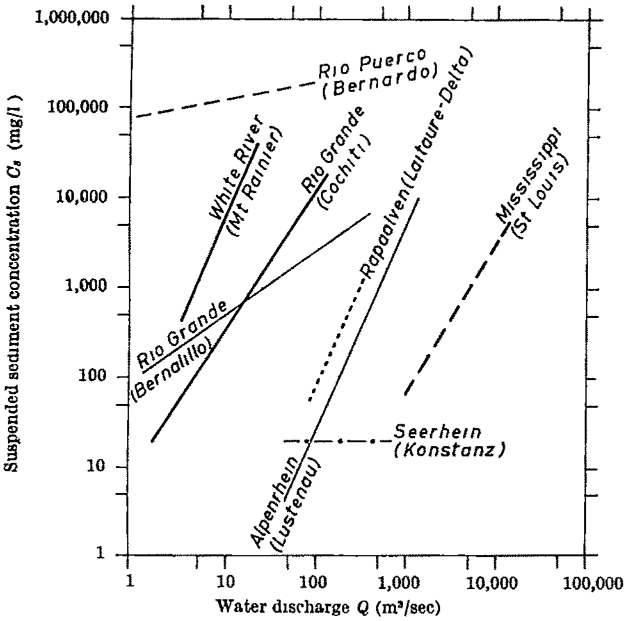

Fig. 3. Suspended sediment concentration versus water discharge of different rivers at single localities.

In this equation, the rivers shown in Table 1 are in the range 5 to 80,000 for x and 0 to 8 for y.

In Table 1 the rivers are arranged in order of increasing exponents b and y, respectively, which are measures of the slope of the curves in Fig. 2. Usually these exponents seem to express the intensity of the erosional forces which are determined chiefly by the gradient and the cross-section of a river channel. In the Seerhein at Konstanz, no erosion at all is effective (b and $y = 0$), while Rapaalven, the Alpenrhein and the White River are typical mountain rivers with high relief energy ($b = 2.2$ to 2.5, $y = 4.5$ to 8).

Table 1. NUMERICAL VALUES FOR a, b, x AND y FOR DIFFERENT RIVERS AT SINGLE LOCALITIES

	$C_s = a\ Q^b$		$C_s = x\ V^y$		
River	a	b	x	y	References
Seerhein (Konstanz)	20	0.0	20	0.0	1
Rio Puerco (Bernardo, N. Mex.)	80,000	0.2	80,000	0.8	5
Rio Grande (Bernalillo)	100	0.7	2,000	1.0	6
Rio Grande (Cochiti, N. Mex.)	10	1.5	200	4.0	6
Mississippi (St. Louis)	0.01	1.6	300	4.0	7
Rapaalven (Laitaure-Delta)	0.04	2.2	700	4.5	8
Alpenrhein (Lustenau)	0.004	2.2	5	6.0	1 and unpublished work of G. Muller and U. Forstner
White River (Mt. Rainier, Wash.)	40	2.5	40	8.0	9

Factor a (or x) is large in rivers which drain areas with a high intensity of weathering or a high erodibility of the outcropping rocks or rapid changes in the channel geometry or any combination of these three. An extreme case in which all these factors coincide is the Rio Puerco at Bernardo, an ephemeral stream in which rainstorms cause large mudflows after long dry periods. In the hinterland of the Alpenrhein and the White River, weathering caused by the alpine climate and vegetation is low, channel changes do not occur and rock erodibility is generally low.

It is to be expected that relationships between suspended sediment load and water discharge are easy to obtain from any river at any cross-section. If the relationships are such that they can be expressed by a simple function, prediction of a long-term sediment transport can be readily established.

Depth Habitats of Pelagic Foraminifera during the Pleistocene

PLANKTONIC foraminifera, numbering about thirty modern species, have been found alive not only near the surface but as deep as 2,000 m (ref. 1). Emiliani[2] analysed the O^{18}/O^{16} composition of the shells of several species and concluded that different species occupy different depth habitats, with *Globigerinoides ruber* and *G. sacculifera* living very close to the ocean surface, *Globigerina* spp. living somewhat deeper and *Globorotalia* spp. occupying the deepest habitats down to about 200 m for population averages. Whereas O^{18}/O^{16} analysis of the carbonate shells can only establish the depth at which average shell deposition takes place, not only for individual shells but for entire populations, recent work by Jones[3], using opening and closing plankton nets, has shown that the conclusions reached by Emiliani[2] are essentially correct. It therefore seems that the average depths of shell deposition are also the average depths at which the different species live.

In the present study, the work initiated by Emiliani[2] has been extended through different glacial and interglacial intervals as shown by the deep-sea core *P*6304–8 from the central Caribbean (14° 59′ N., 69° 20′ W., 3,927 m deep, 1,054 cm long). This core has been analysed both isotopically[4] and micropalaeontologically[5] and shown to represent a continuous and undisturbed section of pelagic sediments extending in time back to 275,000 yr ago. Four complete temperature cycles, plus the post-glacial, are represented in this core. All planktonic foraminiferal species present in sufficient abundance were separated from each one of the warm (10, 300, 550, 800 and 1,010 cm below top) and cold (70, 370, 690 and 890 cm below top) stages of the core as indicated by the oxygen isotopic analysis of Emiliani[4]. In addition, a sample showing intermediate temperatures (150 cm below top) was also studied. A total of fourteen species was separated from the samples.

The monospecific samples were crushed, washed in distilled water and directly reacted with 100 per cent H_3PO_4 acid (compare ref. 4). The carbon dioxide gas thus obtained was analysed with a high-precision Nier–Urey mass spectrometer. The results are shown in Tables 1 and 2. The different species have been arranged in order of decreasing temperatures for both the 10 cm level (post-glacial) (Table 3) and for the averages of all warm and cold stages (Table 4). The sequence is usually the same. Corresponding water depths have been calculated using the Atlas published by Fuglister[6].

The following conclusions can be drawn from Table 3: the four species and subspecies of *Globigerinoides* occupy

the shallowest habitats (top 40 m), the six species and subspecies of *Globorotalia* occupy the deeper habitats (120 to about 200 m), and *Orbulina universa, Pulleniatina obliquiloculata, Hastigerina pelagica* and *Sphaeroidinella dehiscens* occupy intermediate depths (80 to 110 m)

The temperature–depth distribution obtained from the sample at 10 cm in core *P*6304–8 is compared with the observed temperature and depth distribution obtained by Jones[3] for a station in the equatorial Atlantic (0° 2 5′ S, 7° 55′ W) This comparison (Table 5) shows general agreement, except for *Hastigerina pelagica* Jones noted, however, that the depth distribution of *H pelagica* was unexpected and contrary to most previously reported occurrences, which usually indicate a warm, upper water habitat

Emiliani[4,7] stated that a portion of the amplitude of the isotopic ratios in pelagic foraminiferal shells from warm and cold stages of Pleistocene cores is a result of variations in the oxygen isotopic composition of the sea water He estimated this portion to be about 30 per cent[4]. Olausson[8] and Shackleton[9], on the other hand, claim that the entire measured amplitude is caused by variations in the isotopic composition of the sea water In Fig 1 is a plot of the warm/cold amplitude of the isotopic variations for the different species against mean warm stage isotopic composition A gross relationship is shown, with the deeper species (*Globorotalia tumida, G truncatulinoides* and *G crassaformis*) exhibiting the smallest amplitude This amplitude is about 50 per cent of that given by the shallower species, and so we conclude that variations in the isotopic composition of the sea water cannot account for more than half of the isotopic variations measured in the foraminiferal shells

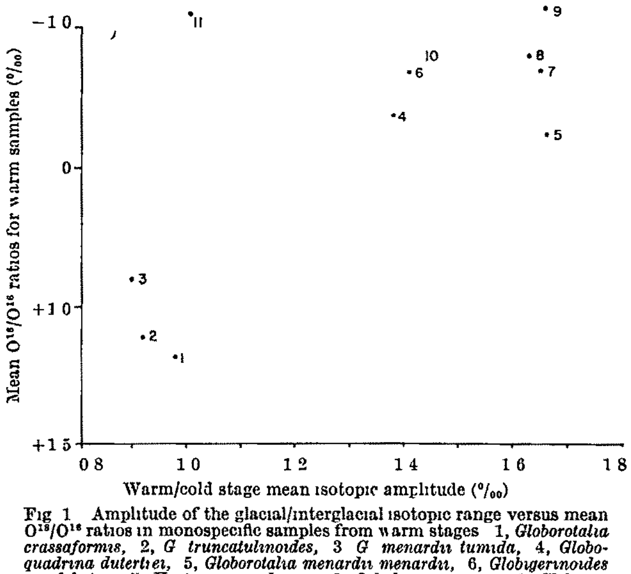

Fig 1 Amplitude of the glacial/interglacial isotopic range versus mean O^{18}/O^{16} ratios in monospecific samples from warm stages 1, *Globorotalia crassaformis*, 2, *G truncatulinoides*, 3 *G menardii tumida*, 4, *Globoquadrina dutertrei*, 5, *Globorotalia menardii menardii*, 6, *Globigerinoides conglobatus*, 7, *Hastigerina pelagica*, 8, *Orbulina universa*, 9, *Globigerinoides trilobus sacculifera*, 10, *G trilobus trilobus*, 11, *G ruber*

MOLECULAR STRUCTURE

Further X-ray Evidence of Regularly Distributed Lysine in α-Keratin

IT has recently been shown that in mohair fibres the fifth order of the 198 Å pseudo repeat (39 Å reflexion) is intensified when the ε-amino groups of lysine residues are acylated with 3,4,5-triiodobenzoic acid *p*-nitrophenylester[1] Particularly high yields of acylated ε-amino groups were obtained when dimethylsulphoxide was used as reaction medium A sample of mohair which had been treated for 24 h at 40° C in this solvent, however, showed a somewhat diffuse X-ray pattern We therefore looked for a reaction medium which did not cause structural distortion of the α-keratin and which gave high yields of acylated ε-amino groups
